Peristenus relictus (stygicus) (Hymenoptera: Braconidae) A Possible Biological Control Agent For Tarnished Plant Bug, Lygus lineolaris, (Hemiptera: Miridae) In New Jersey

Annual Report 2014

Prepared by:

Wayne Hudson George Robbins Thomas Dorsey Mark Mayer Elizabeth Rooney Lauren Bronhard

Phillip Alampi Beneficial Insect Laboratory Division of Plant Industry http://www.nj.gov/agriculture/divisions/pi/prog/biological.html

INTRODUCTION

Tarnished plant bug, (TPB), Lygus lineolaris, (Hemiptera: Miridae) (Figure 1) is a piercing sucking insect native to North America that feeds on over 300 plant species and causes at least two billion dollars in losses and control costs each year (Day 2002). Adults over-winter under leaf litter and become active during the first warm days of spring. Mating and oviposition occur within days and females lay 30 to 120 eggs during their lifespan. Eggs hatch within 10 - 12 days with life cycle completion in 3 to 4 weeks. Generally, there are 3 generations per year in New Jersey (Chianese 2001).

Figure 1. Tarnished plant bugs in rearing box.

The tarnished plant bug is widely distributed, and is present in all states east of the Rocky Mountains where it is a pest of many agricultural crops including vegetables, fruits and seed crops (Schwartz and Footit 1998). Feeding damage to these crops frequently goes unnoticed because there are no visible signs of TPB feeding so crop damage is not obvious until weeks after feeding has occurred (Day 2002). The injury causes a reduction in yield due to a severe distortion of fruit or plant terminals. Growers routinely use broad-spectrum insecticides as a prophylactic treatment on high value crops however, these spray treatments may cause secondary pest problems by reducing beneficial insect populations that keep minor agricultural pests at tolerable levels.

In early spring, the majority of TPB damage occurs on tree fruit, due to the reservoir of TPB found in the blooming annual weeds. The TPB feeds on these weeds and as the weeds die or senesce, they move up onto the developing fruit buds, blossoms and young fruit. (PSU 2000). Damaged flower clusters appear dried and the leaves have a distorted appearance. The damage to the fruit is the major concern, because it can cause punctures or deep dimples to form as the fruit develops, resulting in deformities known as "cat facing" (Spangler et. al. 1991). In New Jersey, the TPB and other "cat facing" insects are the single largest cause for insect fruit damage in peaches statewide and over most varieties" according to Rutgers Cooperative Extension Fruit IPM coordinator Dean Polk (Chianese 2001).

The TPB has a number of natural enemies such as other true bugs (nabids, geocorids), ladybird beetles, spiders and parasitic wasps, but they are not able to effectively control the pest (Spangler et. al.1991). In an attempt to reduce indigenous TPB populations, the United States Department of Agriculture – Agricultural Research Service (USDA-ARS) introduced two species of European parasitoids, *Peristenus digoneutis* and *Peristenus relictus (stygicus)* (Hymenoptera: Braconidae) (Figure 2). These multivoltine species have been found to parasitize significant numbers of TPB nymphs in certain forage crops and strawberries (Day and Tatman 2005, unpublished data). In addition, *P. digoneutis* has also been shown to reduce "cat facing" damage to apples in New Hampshire by 63% (Day 2003).

Figure 2. P. relictus attacking tarnished plant bug nymph (L) and adult female (R).

Dr. William Day of USDA-ARS released *P. digoneutis*, a native of Northern Europe, in New Jersey in the early 1980's. The parasitoid became well established in Northwestern New Jersey by 1988 (Day, et. al. 1990), and had not been recovered south of Hunterdon County until the New Jersey Department of Agriculture recovered it in 2003 in Gloucester County. Researchers hypothesized that the Southern New Jersey climate was not as conducive to the establishment of *P. digoneutis*, which thrives in a more northerly European climes. Another parasitoid, *P. relictus* was imported from Southern Europe, where the climatic match is near that found in Central and Southern NJ; the regions where most of the high cash crops such as peaches, apples and strawberries are grown.

MATERIALS AND METHODS

In the fall of 2000, field staff from PABIL, using standard insect sweep nets, surveyed alfalfa, hay, and fallow fields for the presence of TPB. The sweep surveys resulted in a list of possible locations for initial parasitoid releases. Survey results, were also used to establish baseline TPB population data and native parasitoid occurrence.

The original 2001 Whig Lane and subsequent 2002-2003 Cedar Road release sites were in Gloucester County alfalfa fields surrounded by and in close proximity to both apple and peach orchards. These fields were minimally disturbed, seldom treated with insecticides and the growers' alfalfa management practice of harvesting in strips staggered throughout the growing season at the release sites was favorable for parasitoid development and establishment. This practice maintained some TPB in the field, providing a continuous reservoir of nymphs for parasitism by *P. relictus*.

The "uncut strips" in the release field were sampled weekly using standard insect sweep nets (Figure 3) with samples consisting of 100 sweeps/field. The collections were placed into a sleeve cage (Figure 4) and the number of TPB adults and nymphs were counted and recorded. If a minimum number of 100 TPB nymphs was not collected in the first 100-sweep sample then additional sweeps were taken until 100 nymphs were collected. The nymphs were packaged, kept cool overnight, and transported to the PABIL, where they were set to recover the parasites.

Figure 3. Sweeping for TPB

Figure 4. Sleeve cage

In 2004, two additional release sites were set up, one in Mantua Township, Gloucester County and the other at the Rutgers Research Farm in Upper Deerfield Township, Cumberland County. The same sampling procedures used for 2001-2003 was followed at both of the new sites. The new sites were on "set-aside" or fallow ground with high weed populations. Marestail, *Conyza canadensis* (Asteraceae) was the prominent weed species at both sites. Preliminary field observations in 2000 found high TPB populations in weedy locations and weedy fields were less disturbed by normal harvesting and cultivating practices.

During the 2005 season, three new alfalfa field s were added to the program. The sites were in Vineland in Cumberland County and Mannington in Salem County. The 2004 Cumberland County site at Rutgers Centerton Farm was strip-planted with wild flowers to attract more TPB and provide a more diverse weed population. The Phillip Alampi Beneficial Insect Laboratory also implemented a new laboratory-rearing technique using an artificial diet in that gave the laboratory the ability to produce substantially more *P. relictus* than previous years shown in Table 1.

Table 1. Peristenus relictus Releases in New Jersey

Release Year	Number of Sites	Number Released
2001	1	250
2002	1	1,650
2003	1	930
2004	2	3,400
2005	10	18,625
2006	13	21,500
2007	23	40,000
2008	39	51,000
2009	20	15,800
2010	11	4,700
2011	16	28,750
2012	14	11,500
2013	8	11,750
2014	8	21,500
Total		231,355

In 2006, PABIL entered into a cooperative agreement with the USDA-ARS and Delaware State University to produce, release and monitor *P. relictus* in Delaware and New Jersey. Under the terms of the agreement, PABIL would provide parasitized *L. lineolaris* nymphs and adult *P. relictus* for New Jersey and Delaware release. There were six alfalfa study sites consisting of two *P. relictus* adult release sites, two parasitized TPB nymph release sites and two control sites in each state. Delaware cooperators were responsible for processing of weekly nymph collections from both states, as well as rearing and dissecting a portion of the collections.

RESULTS AND DISCUSSION

In 2014, field staff targeted sampling sites in areas that received high concentrations of releases in the past with the surveys beginning in June and continuing through September. The reason for this procedural change was that in theory, the areas that received large numbers of releases in successive years should have high numbers of parasites, and that the resulting collections would yield the best probability for parasite recovery. Between July 9 and October 2, field personnel made eight nymphal collections. The collections were transported to the laboratory, processed, and set up to recover the parasitoids. Only two species of Braconid were recovered in 2014, the native species *Leiophron uniformis*, and *P. digoneutis*. Table 2 shows the total number of *Peristenus* recovery locations by township and location from 2004-2014 which can also be viewed graphically in Figure 5. It was expected that *P. relictus* recoveries would increase over

time once the weather conditions are more conducive for an increase in the tarnished plant bug populations but 2010 was only year where substantial recoveries were made and all of those were *P. digoneutis*. The lack of *P. relictus* recoveries is concern although *P. digoneutis* was recovered almost a decade after the first releases (Day, et. al. 1990). If *P. relictus* is present, it should start to show up. Halloran and Tumlinson (2011) showed that *Lygus* spp. are attracted more to flowers and weeds so we might be looking for the parasites in the wrong locations, i.e. an alfalfa field versus wildflowers.

Figure 6 shows the location of the release fields and any parasitoid recoveries. *P. digoneutis* continues to be recovered by field staff in South Jersey, although not in high numbers. *P. digoneutis* was recovered by field personnel in Cape May in 2010 and that is the first recovery in South Jersey outside the initial survey area of Salem/Gloucester/Cumberland Counties.

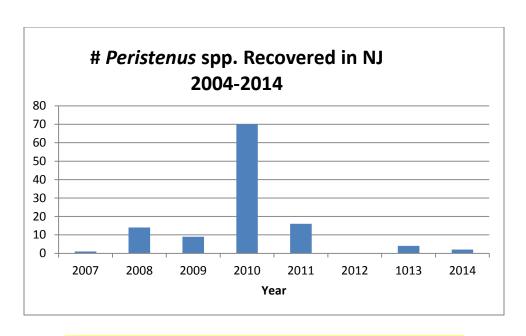

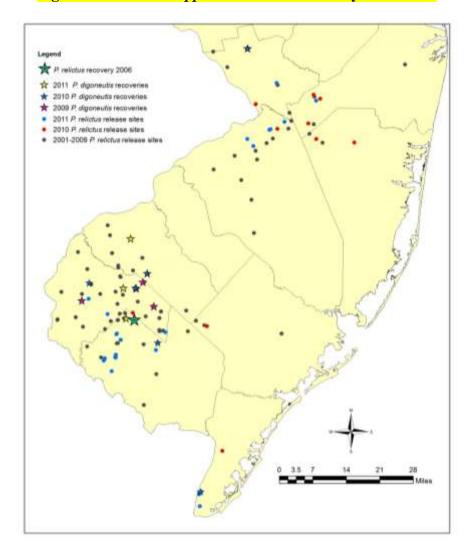

Figure 6. Peristenus spp. Release and Recovery Sites in NJ

Despite the 231,355 *P. relictus* that have been released in the state, only one recovery of that species has been made in South Jersey. As stated previously, Day, et. al. (1990) showed that another species, *P. digoneutis*, was not recovered until the late 80's after the initial releases so it might be too soon to expect to recover *P. relictus* but far more *P. relictus* than *P. digoneutis* were released in equivalent periods. The fact that we have not recovered *P. relictus* may possibly be due to other factors 1) *Lygus* spp. prefer weeds to alfalfa so we may have to concentrate on weedy fields versus crops; 2) *P. digoneutis* is in South Jersey and *P. relictus* may not be able to compete with it; 3) the two species may hybridize; 4) The climate may not match well for *P. relictus*; 5) the weather conditions during the survey season may not be conducive to the recovery of the parasites because of insufficient host material.

Conclusion

In 2014, the lack of a *P. digoneutis* being recovered is probably due to the fact that, field collections were down due to program and personnel constraints. In order for *P. relictus* to be recovered and this program to be successful, a significant *Lygus* host population is necessary which was not present during 2014. The recoveries of parasites will be difficult as long as host populations and field collections remain low. This could mean that a much longer period of time will be necessary for the parasites to build up their numbers to noticeable levels such as was the case with *P. digoneutis* (Day, et. al. 1990).

2015 Plans

The same 2014 protocol for surveys and collections will be used in hopes of increasing the chance for recovery but weedy field filled with wildflowers will also be extensively sampled. The 2004 release site where *P. relictus* was initially recovered in 2006 will continue to be highly surveyed. New release sites of *P. relictus* will be at least a ½-mile away from all previous release sites. Releases will begin at the first appearance of nymphs and will continue weekly or biweekly throughout the growing season. Release locations will continue to expand into Burlington, Mercer, Monmouth, and Cape May Counties. Surveys will be conducted in newer areas where there were releases made in the past but no surveys were previously made.
