CONVERSION FACTORS

Factors for converting inch-pound units to metric (International System) units are given below:

<u>Multiply (Inch-Pound-Unit)</u>	<u>By</u>	<u>To Obtain (Metric Unit)</u>
<u>Length</u>		
inch (in.)	25.4	millimeter (mm)
foot (ft)	0.3048	meter (m)
mile (mi)	1.609	kilometer (km)
<u>Area</u>		
square mile (mi ²)	2.590	square kilometer (km ²)
<u>Flow</u>		
cubic foot per second (ft ³ /s)	0.02832	cubic meter per second (m ³ /s)
million gallons per day (Mgal/d)	0.04381	cubic meter per second (m ³ /s)

Temperature Conversion Formula: °F = 1.8°C + 32

Sea Level: In this report "sea level" refers to the National Geodetic Vertical Datum of 1929 (NGVD of 1929)--a geodetic datum derived from a general adjustment of the first order level nets of both the United States and Canada, formerly called "Sea Level Datum of 1929."

WATER-QUALITY DATA FOR THE POTOMAC-RARITAN-MAGOOTHY AQUIFER
SYSTEM IN THE NORTHERN COASTAL PLAIN OF NEW JERSEY, 1923-86

By Douglas A. Harriman, Daryll A. Pope, and Alison D. Gordon

ABSTRACT

Ground-water-quality data for the upper and middle aquifers of the Potomac-Raritan-Magothy aquifer system in Middlesex and Monmouth Counties are compiled for the period 1923-86. A total of 330 wells were sampled: 192 wells in the upper aquifer and 138 wells in the middle aquifer. Most of the complete water-quality analyses were collected after September 1984, as part of a regional ground-water assessment. Well-construction data for the sampled wells also are presented. Public-supply, domestic-supply, industrial, commercial, irrigation, and observation wells were sampled for the study. Field measurements made at the time of sample collection include water temperature, specific conductance, dissolved oxygen, pH, alkalinity, and bicarbonate concentration. Laboratory determinations include common ions, silica, dissolved solids, trace metals, volatile organic compounds, and pesticides. A quality-assurance program was followed to evaluate and assure the quality of the data.

The report also contains a table of lithologic and hydrologic characteristics of the geologic units in the study area, a table of chloride concentrations and field measurements from 1923-86, and statistical summaries of selected water-quality data for the upper and middle aquifers. Many constituents were found in a wide range of concentrations.

Water from more than 25 percent of the wells sampled contained lead concentrations above the detection limit of 10 µg/L (micrograms per liter). Included in this number are some wells that had lead concentrations greater than the U.S. Environmental Protection Agency (USEPA) primary drinking-water regulation of 50 µg/L. Cadmium concentrations, although lower than lead concentrations, followed a similar pattern. Water from approximately 25 percent of the wells in the upper aquifer, contain cadmium concentrations equal to or greater than the detection limit of 1 µg/L.

Dissolved iron concentrations ranged from 5 µg/L to 480,000 µg/L. Water from more than 50 percent of the wells sampled contained iron concentrations in excess of the USEPA secondary drinking-water recommended limit of 300 µg/L.

Chloride concentrations greater than the USEPA secondary drinking-water recommended limit of 250 milligrams per liter were found in samples from wells located in the cities of Perth Amboy and South Amboy; in the boroughs of Keansburg, Sayreville, Keyport, and Union Beach; and in the townships of Old Bridge and Woodbridge.

Of 21 samples collected from wells screened in the upper aquifer and analyzed for 30 volatile organic compounds (VOCs), 5 samples contained at least 1 VOC at or above the detection limit. In the middle aquifer, 12 of the 21 samples collected and analyzed for VOCs contained at least 1 VOC greater than the detection limit.

Concentrations of pesticides generally were low. Of the 43 samples collected from wells screened in the upper aquifer and analyzed for pesticides, 4 samples contained concentrations of pesticides at or greater than the detection limit. In the middle aquifer, 6 of 38 samples collected and analyzed for 32 pesticides had at least 1 pesticide with a concentration greater than the detection limit.

INTRODUCTION

Ground water from the Potomac-Raritan-Magothy aquifer system is the major potable water source in the 600-square mile study area (fig. 1). During 1980, ground-water withdrawals for public supply, industrial, commercial, and agricultural uses in the Coastal Plain part of Middlesex County were about 48 Mgall/d (million gallons per day); in Monmouth County, they were about 33 Mgall/d (Vowinkel, 1984, p. 19). Approximately 90 percent of these withdrawals were from the Potomac-Raritan-Magothy aquifer system.

Land development in the area is increasing with the growth in population. The resulting changes in land use and increases in ground-water withdrawals can affect the quality of ground water in the Potomac-Raritan-Magothy aquifer system; however, the effects of local contamination and development on the regional water quality in the area are largely unknown.

In addition, declining water levels in the Potomac-Raritan-Magothy aquifer system have caused saltwater to intrude into the aquifer system through submerged outcrop areas. This has increased the potential for lateral movement of the regional saltwater transition zones toward pumping centers (Leahy, 1985, p. 18). Saltwater contamination of wells has occurred in some areas near the coast, including parts of Keyport and Union Beach Boroughs in Monmouth County (Schaefer and Walker, 1981), and Sayreville Borough, South River Borough, and South Amboy City in Middlesex County (Schaefer, 1983).

Purpose and Scope

The purpose of this report is to present the water-quality data collected from 1923-86 for the upper and middle aquifers of the Potomac-Raritan-Magothy aquifer system in the study area. A total of 330 wells were sampled: 192 wells in the upper aquifer and 138 wells in the middle aquifer. Most of the complete water-quality analyses were collected after September 1984. This report includes tables of water-quality data, a table of wells where pesticide or volatile organic compounds were detected, and well-construction data for the sampled wells. Statistical summaries of results of the chemical analyses are tabulated for each aquifer, and the locations of sampled wells are shown on plates 1 and 2. This report was prepared in cooperation with the New Jersey Department of Environmental Protection, Division of Water Resources. It is one of a series of products originating from the South River vicinity ground-water investigation, a study funded by the New Jersey Water-Supply Bond of 1981.

Hydrogeologic Setting

The Coastal Plain sediments of New Jersey overlie a pre-Cretaceous basement. The Coastal Plain hydrogeologic units (aquifers and confining

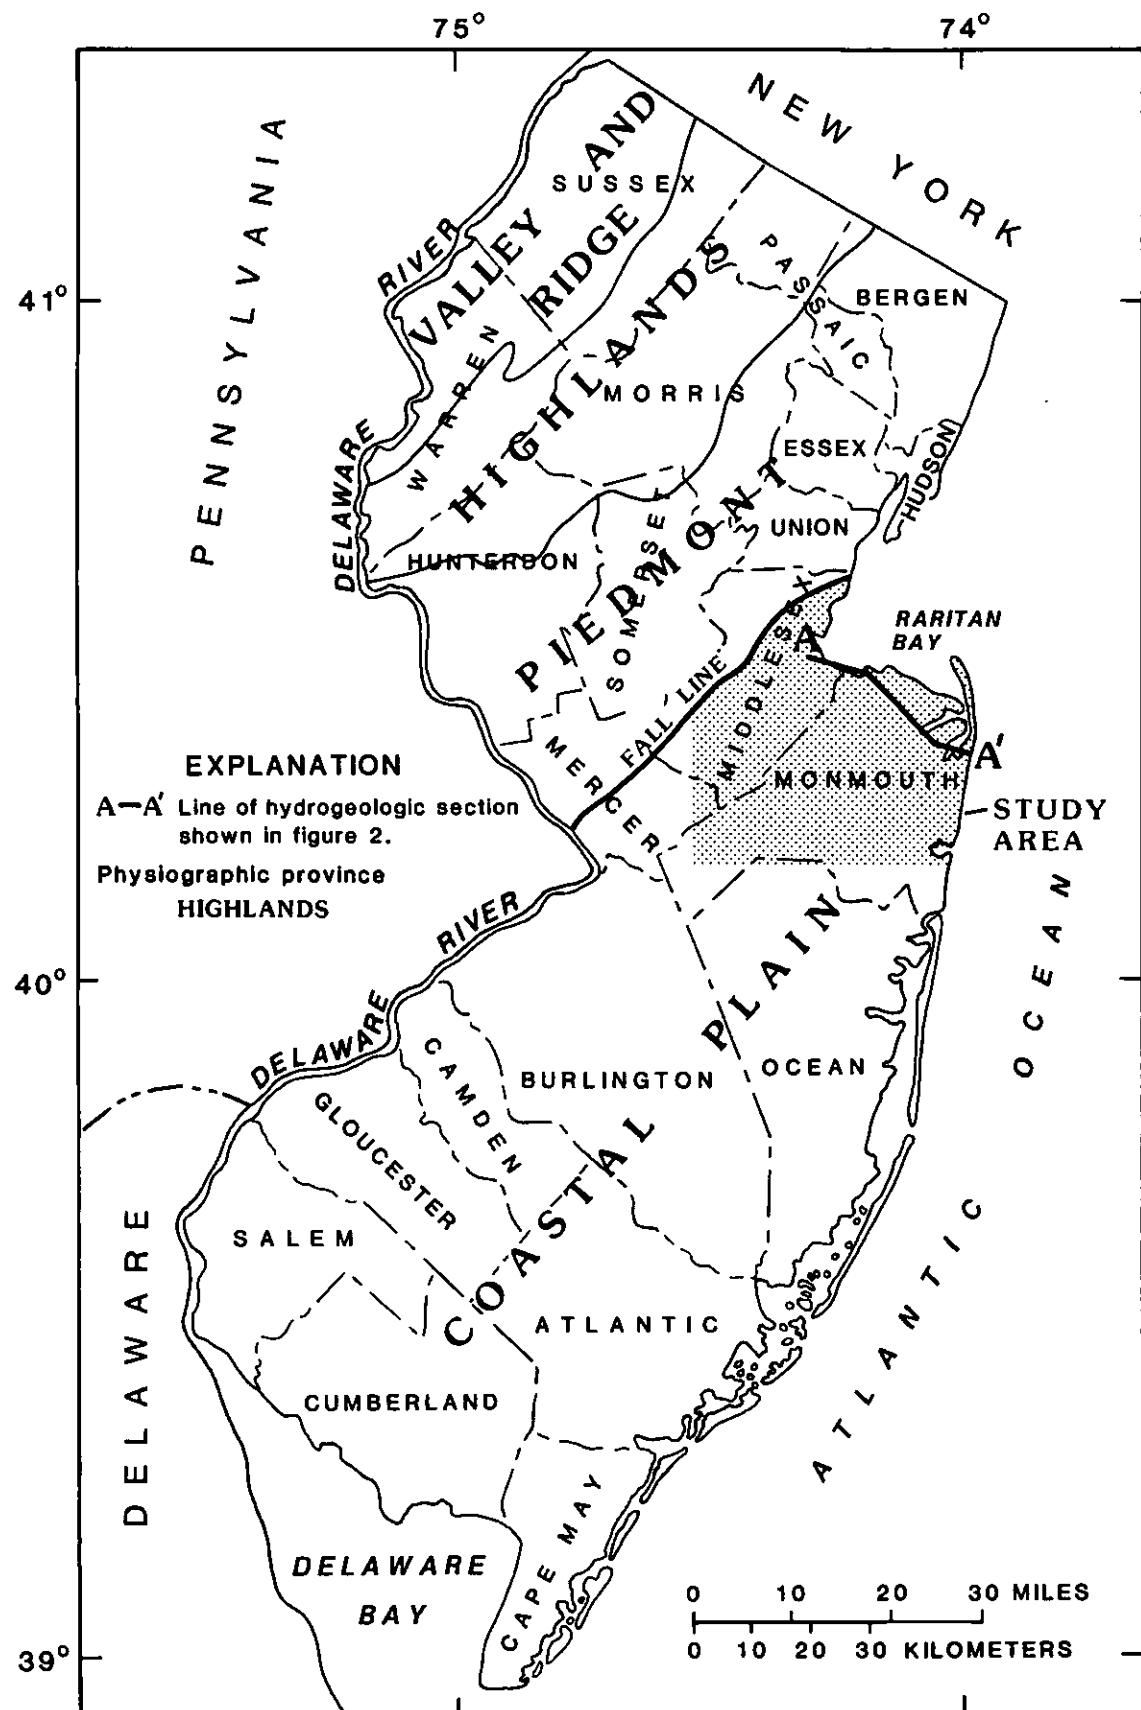

Figure 1.--Location of study area in New Jersey and line of hydrogeologic section.

Table 1.--Geologic and hydrogeologic units in the Coastal Plain of New Jersey

SYSTEM	SERIES	GEOLIC UNIT	LITHOLOGY	HYDROGEOLOGIC UNIT	HYDROLOGIC CHARACTERISTICS
Quaternary	Holocene	Alluvial deposits	Sand, silt, and black mud.	Undifferentiated	Surficial material, commonly hydraulically connected to underlying aquifers. Locally some units may act as confining units. Thicker sands are capable of yielding large quantities of water.
		Beach sand and gravel	Sand, quartz, light-colored, medium-to coarse-grained, pebbly.		
	Pleistocene	Cape May Formation			
Tertiary	Miocene	Pensauken Formation	Sand, quartz, light-colored, heterogeneous clayey, pebbly.	Kirkwood-Cohansey aquifer system	A major aquifer system. Ground water occurs generally under water-table conditions. In Cape May County the Cohansey Sand is under artesian conditions.
		Bridgeton Formation			
		Beacon Hill Gravel	Gravel, quartz, light colored, sandy.		
		Cohansey Sand	Sand, quartz, light-colored, medium to coarse-grained, pebbly; local clay beds.		
		Kirkwood Formation	Sand, quartz, gray and tan, very fine-to, medium-grained, micaceous, and dark-colored diatomaceous clay.		
	Oligocene	Piney Point Formation	Sand, quartz and glauconite, fine-to coarse-grained.	Confining unit	Thick diatomaceous clay bed occurs along coast and for a short distance inland. A thin water-bearing sand is present in the middle of this unit.
		Shark River Formation			
		Manasquan Formation	Clay, silty and sandy, glauconitic, green, gray and brown, fine grained quartz sand.		
	Paleocene	Vincentown Formation	Sand, quartz, gray and green, fine-to coarse-grained, glauconitic, and brown clayey, very fossiliferous, glauconite and quartz calcarenous.	Vincentown confining unit	Yields small to moderate quantities of water in and near its outcrop area.
		Hornerstown Sand	Sand, clayey, glauconitic, dark green, fine to coarse-grained.		
Cretaceous	Upper Cretaceous	Tinton Sand	Sand, quartz, and glauconite, brown and gray, fine-to coarse-grained, clayey, micaceous.	Composite	Poorly permeable sediments.
		Red Bank Sand			
		Navesink Formation	sand, clayey, silty, glauconitic, green and black, medium-to coarse-grained.		
		Mount Laurel Sand	sand, quartz, brown and gray, fine-to coarse-grained, slightly glauconitic.	Wenonah-Mount Laurel aquifer	A major aquifer.
		Wenonah Formation	sand, very fine-to fine-grained, gray and brown, silty, slightly glauconitic.		
		Marshalltown Formation	Clay, silty, dark greenish gray, glauconitic quartz sand.	Marshalltown-Wenonah confining unit	A leaky confining unit.
		Englishtown Formation	sand, quartz, tan and gray, fine-to medium-grained; local clay beds.	Englishtown aquifer system	A major aquifer. Two sand units in Monmouth and Ocean Counties.
		Woodbury Clay	Clay, gray and black, micaceous silt.		
	Lower Cretaceous	Merchantville Formation	Clay, glauconitic, micaceous, gray and black; locally very fine-grained quartz and glauconitic sand.	Merchantville-Woodbury confining unit	A major confining unit. Locally the Merchantville Formation may contain a thin water-bearing sand.
		Hegemony Formation	Sand, quartz, light-gray, fine-to coarse-grained. Local beds of dark-gray lignitic clay.		
		Raritan Formation	Sand, quartz, light-gray, fine-to coarse-grained, pebbly, arkosic, red, white, and variegated clay.	Potowomut-Harrington aquifer system	A major aquifer system. In the northern Coastal Plain, the upper aquifer is equivalent to the Old Bridge aquifer, the middle aquifer is equivalent to the Farrington aquifer. In the Delaware River Valley three aquifers are recognized. In the deeper subsurface, units below the upper aquifer are undifferentiated.
		Potomac Group	Alternating clay, silt, sand, and gravel.		
Pre-Cretaceous	Bedrock	Precambrian and lower Paleozoic crystalline rocks, metamorphic schist and gneiss; locally Triassic sandstone, shale and Jurassic basalt.	Bedrock confining unit		

Modified from Zapesz, 1984, table 1

units) do not always coincide with the geologic units (Zapecza, 1984, p. 9). The names of individual geologic and hydrogeologic units, and their lithologies, are given in table 1.

Figure 2 shows a representative hydrogeologic section through the study area. Zapecza (1984) describes the subsurface occurrence and configuration of hydrogeologic units in the New Jersey Coastal Plain. Discussion of hydrogeologic units in this report is limited to those units within the Potomac-Raritan-Magothy aquifer system and the overlying confining unit. The Potomac-Raritan-Magothy aquifer system is composed primarily of an upper aquifer, a middle aquifer, and a lower aquifer. Each aquifer is separated by a confining unit. The lower aquifer is not present in the study area.

The overlying confining unit is composed primarily of the Merchantville Formation and the Woodbury Clay. It also includes the Amboy Stoneware Clay Member and the discontinuous Cliffwood and Morgan beds.

The upper aquifer of the Potomac-Raritan-Magothy aquifer system is composed primarily of the Old Bridge Sand Member of the Magothy Formation. Where the South Amboy Fire Clay Member is thin or missing, the Sayreville Sand Member of the Raritan Formation also is part of the aquifer (Farlekas, 1979, p. 22). The upper aquifer is characterized by coarse-grained sands and gravels.

The confining unit between the upper and middle aquifers is formed by the Woodbridge Clay Member of the Raritan Formation. Locally, this confining unit also includes the Sayreville Sand Member and the South Amboy Fire Clay Member of the Raritan Formation.

The middle aquifer of the Potomac-Raritan-Magothy aquifer system is composed of the Farrington Sand Member of the Raritan Formation in most of central New Jersey (Zapecza, 1984 and Farlekas, 1979, p. 8). This sand member is characterized by sands and gravels with lenses of clay. In downdip areas of Monmouth County, the middle aquifer also includes the uppermost sands of the Potomac Group (Farlekas, 1979, p. 9). The lower confining unit, where it exists, consists of the Raritan fire clay of the Raritan Formation and the pre-Cretaceous basement bedrock.

Well-Numbering System

The well-numbering system used in this report was developed by the New Jersey District, U.S. Geological Survey, for the Ground-Water Site Inventory (GWSI) data base. The NJ-WRD well number consists of a two-digit county code and a sequence number for the well within the county. County codes used in this report are 23 for Middlesex County and 25 for Monmouth County.

Acknowledgments

The assistance of state and municipal officials, industry representatives, and individuals is gratefully acknowledged for providing well information and permitting access to wells for the collection of water samples.

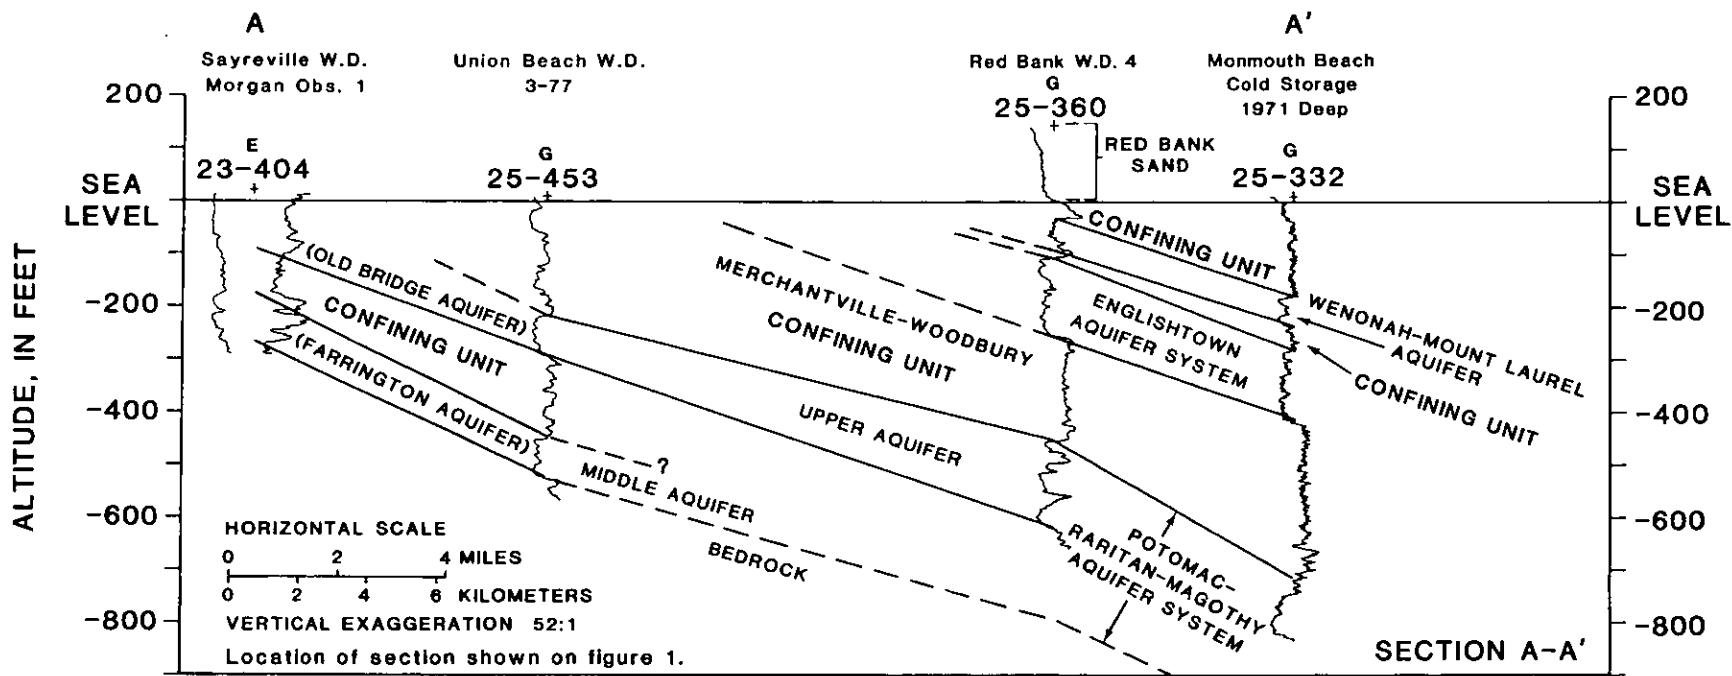

Figure 2.--Hydrogeologic section through study area. (From Zapecza, 1984, plate 3).

DATA COLLECTION AND ANALYSIS

Well Selection

The major objective of the 1984-86 sampling program was to characterize the regional ground-water quality. Wells were selected to provide a relatively uniform distribution of sampling points throughout the study area. However, to more fully characterize the water quality, other considerations had to be taken into account. Because ground-water quality can be altered as it moves through the aquifers (Back, 1966, p. A15), wells were selected from areas where flow paths remain similar to predevelopment conditions and from areas where withdrawals have significantly altered the flow system. Clusters of two or more wells with screen intervals set at different depths were chosen to allow for comparisons of water quality at different depths. Wells also were selected in areas where saltwater intrusion has occurred. In previous years, many of these wells had numerous samples collected for chloride determinations, but lacked more complete water-quality data.

Wells were selected primarily from the Ground-Water Site Inventory (GWSI) data base. All the wells chosen for sampling are screened in only one aquifer. In areas where suitable wells were not found in GWSI, well records of additional wells were obtained from the N.J. Department of Environmental Protection. These additional wells were field checked prior to sampling, and the appropriate data were entered into GWSI. Table 2 contains well-construction data and water-use information for the sampled wells. The data are grouped by county and sorted by well number. The locations of the sampled wells and delineation of outcrops (U.S. Geological Survey, 1967 and Barksdale and others, 1943) are shown on plates 1 and 2.

Water samples were collected from a variety of pumped wells, observation wells, and unused wells. An effort was made to select wells having a wide range of pump capacities so that the data collected would provide different types of water-quality information. For example, large-capacity wells draw water from a large volume of an aquifer; therefore, they represent the average water quality within the aquifer in the vicinity of the well (Wood, 1976, p. 4). Small-capacity wells draw water from a much smaller volume of the aquifer; therefore, they represent the water quality at one point in the aquifer.

Sample-Collection Methods

Methods used to collect and preserve samples for water-quality analysis by the Survey are discussed in Brown and others (1970), Goerlitz and Brown (1972), and Wood (1976). Fusillo and others (1984, p. 6) outlines the changes that have taken place in these methods from 1923 through 1983.

All samples consisted of raw (untreated) water. At most wells, water was collected from a tap near the wellhead. At a few wells, water passed through a small holding tank prior to collection. Wells that were not heavily used were sampled only after evacuating a minimum of at least two well-casing volumes of water. Stabilization of water temperature, specific conductance, and pH at these wells was a prerequisite for sample collection (Wood 1976, p. 4).

At each sampled well, the following field measurements were typically made: water temperature, specific conductance, dissolved oxygen, pH, alkalinity, and bicarbonate concentration. Ground-water samples were collected, processed, and preserved according to methods described in Wood (1976), Brown and others (1970), and Goerlitz and Brown (1972).

Analysis of samples for certain constituents required that some combination of filtering, preserving, and chilling be provided in the field. For dissolved metals, samples were filtered through a 0.45 μm (micrometer) filter and acidified with nitric acid to a pH of 2.0 or lower. To determine nitrogen and phosphorus species, samples were filtered and preserved in opaque bottles with mercuric chloride and kept chilled at 4 °C (Celsius). For dissolved organic carbon, samples were filtered through a 0.45- μm silver filter into a glass bottle and chilled at 4 °C. For volatile organic compounds (VOCs), four replicate samples were collected in 40-mL (milliliter) glass septum bottles and chilled at 4 °C.

Laboratory Analysis

Two different U.S. Geological Survey laboratories analyzed samples for the study: the Atlanta National Water-Quality Laboratory in Doraville, Georgia and the Denver Central Laboratory in Arvada, Colorado. In addition to these laboratories, the New Jersey District Laboratory performed a scan for volatile organic compounds on samples using a gas chromatograph.

Water samples were analyzed using U.S. Geological Survey methods for the water-quality constituents listed in table 3. All analyses resulting from samples collected for the study were checked as described in the Quality-Assurance Program section of this report. The laboratory analytical methods that were used are discussed in Fusillo and others (1984, p. 8). The analytical methods used to determine concentrations of constituents in samples collected during the 1984-86 sampling program are described in Fishman and Friedman (1985). Cations were determined by the inductively-coupled radiofrequency plasma (ICP) method (Fishman and Friedman, 1985, p. 49-50 and 659-671).

The District Laboratory's gas chromatographic (GC) scan can identify 30 VOCs (table 3) (James Kammer and Jacob Gibbs, U.S. Geological Survey, written commun., 1988). Methods 601 and 602 of the U.S. Environmental Protection Agency (1984) are followed. Compounds detected in the scan are identified based on retention time and relative response by two detectors: a photoionization detector and a Hall¹ electrolytic conductivity detector. A standard curve is developed for each compound in the scan. At least one surrogate compound is added to each sample, and at least one blank and one spiked blank are run for each set of 10 analyses. A concentration range for a detected compound is estimated by applying the standard curve to the integrated peak area on the chromatogram.

¹ The use of trade names in this report is for identification purposes only and does not constitute endorsement by the U.S. Geological Survey.

Total Organophosphorus Insecticides

Diazinon	Ethion	Malathion
Methyl parathion	Methyl trithion	Parathion
Trithion		

Total Triazine Herbicides

Ametryne	Atrazine	Cyanazine
Prometone	Prometryne	Propazine
Simazine	Simetryn	

Total Volatile Organic Compounds

Chloromethane	Bromomethane
Vinyl chloride	Chloroethane
Methylene chloride	1,1-Dichloroethene
1,1-Dichloroethane	1,2-Dichloroethene
Chloroform	1,2-Dichloroethane
1,1,1-Trichloroethane	Carbon tetrachloride
Dichlorobromomethane	1,2-Dichloropropane
trans-1,3-Dichloropropene	Trichloroethene
Chlorodibromomethane	1,1,2-Trichloroethane
cis-1,3-Dichloropropene	2-Chloroethylvinylether
Bromoform	1,1,2,2-Tetrachloroethane
Tetrachloroethene	Chlorobenzene
1,2-Dichlorobenzene	1,3-Dichlorobenzene
1,4-Dichlorobenzene	Benzene
Toluene	Ethylbenzene

¹ Both total and dissolved iron concentrations were determined.

² DDT (1,1,1-Trichloro-2,2-bis(parachlorophenyl)ethane) and DDD (1,1-Dichloro-2,2-bis(parachlorophenyl)ethane) are insecticides. DDE is a metabolite of DDT.

PCBs are Polychlorinated Biphenyls.

PCNs are Polychlorinated Naphthalenes.

When VOCs were found in the District Laboratory scan at a concentration of at least 3 µg/L (micrograms per liter), the detection limit for volatile organic compounds analyzed at the Survey Laboratories, two replicate septum bottles were sent to one of the two Survey laboratories for gas chromatography-mass spectrometry (GC-MS) analysis of the sample. Inadvertently, ten samples that showed positive results on the District GC-MS scan were not analysed at the Survey laboratories.

Quality-Assurance Program

All laboratory results in this report were provided by Survey laboratories. Data collected prior to September 1984 were subjected to laboratory quality-assurance procedures in effect at the time of the analysis (Fusillo and others, 1984, p. 9). A description of quality-assurance methods used to check the data collected from October 1984 through December 1986 are described below.

Quality-assurance for the study included (1) a check of the results of each water-quality analysis, (2) requests for reruns if any aspect of the results was questionable, and (3) submission of quality-assurance samples to the laboratory. The quality-assurance samples, consisting of standard-reference water samples (SRWS) and replicate field samples, were disguised as ordinary well-water samples and sent to the laboratory intermittently throughout the sampling period. Determinations of volatile organic compounds by the District laboratory were checked by sending selected duplicate samples to one of the Survey laboratories for additional analysis.

Each water-quality analysis was checked using procedures described by Friedman and Erdmann (1982, p. 103-105). These procedures included (1) calculation of the ion balance; (2) comparison of field measurements of specific conductance, pH, and alkalinity with corresponding laboratory measurements; and (3) calculation of five different ratios and comparison with ranges recommended by Friedman and Erdmann (1982, p. 103-105). The five ratio checks included (1) dissolved solids to laboratory specific conductance, (2 and 3) cations and anions (in milliequivalents per liter) to specific conductance, (4) dissolved solids to calculated sum of the constituents, and (5) calculated sum of the constituents to field specific conductance. Results of the checks were used to decide whether or not to request laboratory reruns of one or more constituents. Reruns of trace-metals were requested when the concentration was considered high or unusual.

The SRWS were obtained from the U.S. Geological Survey Quality-Assurance Program in Lakewood, Colorado. The most probable concentration of each constituent in a SRWS is determined by sending split samples to a number of laboratories. A mean (the most probable concentration) and standard deviation are calculated for each constituent based on the results obtained from the participating laboratories (Friedman and Erdmann, 1982, p. 67).

Two types of SRWS were used for quality assurance of the laboratory results (1) SRWS for major-constituents (at specific conductances of 138, 294, and 1106 microsiemens per centimeter ($\mu\text{S}/\text{cm}$) and (2) SRWS for trace-metals. For each constituent determined by the laboratory, the number of standard deviations from the SRWS mean was computed and tabulated.

Aluminum, copper, potassium, and zinc had one measurement each that was slightly more than two standard deviations from the mean. Measurements of the other constituents were consistently within two standard deviations of the mean. Plots of the study's SRWS results were compared with similar plots (called control charts) covering the period March 10, 1985, through November 5, 1985, prepared by the U.S. Geological Survey Quality-Assurance Program (Dale Peart, U.S. Geological Survey, written commun., 1985). All of the aluminum and copper measurements on the control plots were within the two standard deviation limit. Only 2 of 130 potassium measurements and 4 of 55 zinc measurements fell outside this limit. Based on these results, major inorganic constituent concentrations and trace-metal concentrations obtained during this period are considered acceptable.

Dissolved nutrients and organic carbon are not included in major-constituent SRWS or trace-metal SRWS analyses. To check laboratory performance on these constituents, replicates of actual ground-water samples were submitted for analysis. Based on results of these analyses, nutrient and organic-carbon data provided by the Survey laboratories are considered acceptable.

As a check on the performance of the District Laboratory's VOC results, duplicate samples were sent to one of the two Survey laboratories. These laboratories performed a GC-MS analysis (Wershaw and others, 1987, p.12) for 27 of the 30 volatile organic compounds in the District Laboratory's GC scan. Other than some minor discrepancies, all concentrations were approximately the same as the District Laboratory values; therefore, VOC data provided by the District Laboratory are considered reliable.

WATER-QUALITY DATA

A total of 380 water-quality analyses are listed in table 4 (in back of text). Of these analyses, 213 are from wells screened in the upper aquifer and 167 are from wells screened in the middle aquifer. This total includes well 25-548 in Matawan Borough, which is screened in sediments of the uppermost Magothy Formation overlying the upper aquifer of the Potomac-Raritan-Magothy aquifer system. The water quality of the sample taken from this well is similar to samples from nearby wells screened in the upper aquifer (wells 25-288, 25-294, and 25-295); therefore, data from this well were included with data from wells screened in the upper aquifer.

Analyses were included in table 4 only if values for either calcium and magnesium, or sulfate and chloride, were available. The data are grouped by aquifer and sorted by well number. Many of the nutrient and trace-metal constituents reported in the table are at or below the detection limits for the analytical methods employed. Constituents not detected in a sample are reported as the value of the detection limit for that particular analysis, preceded by a less than symbol (<). The detection limit for a constituent changed if the sample was diluted or if a different method of analysis was used.

Apparent inconsistencies may exist in some data in table 4. For instance, the total iron concentration may be less than the dissolved iron

concentration. The difference in the inconsistent values, however, is smaller than the precision of the analytical techniques.

The field measurements and inorganic constituents listed in table 3 are included in table 4. Organic carbon and phenols also are individually listed in the table, but total VOCs are lumped together under the heading VOC analysis. Total organochlorine compounds, total organophosphorus insecticides, and total triazine herbicides are lumped together under the heading pesticide analysis. Under the VOC scan heading there are symbols indicating whether or not any VOCs were found at or greater than 0.8 $\mu\text{g/L}$ using the New Jersey District gas chromatograph.

Table 5 (in back of text) lists temperature, specific conductance, and chloride concentrations for ground-water samples collected in the study area for the period 1923-86. These analyses (in addition to chloride) also are listed in table 4 if values for either calcium and magnesium, or sulfate, are available. For samples collected prior to 1975, specific conductance may not have been measured in the field. Therefore, for the period 1923-74, specific conductance is considered to be a laboratory measurement.

Table 6 lists the concentrations of volatile organic and pesticide compounds detected by the U.S. Geological Survey central-laboratory system.

Tables 7 and 8 are statistical summaries of selected water-quality characteristics of water in the upper and middle aquifers, respectively. The most complete analysis for 1984-86 was selected to generate the statistics in the tables. No more than one analysis was used for each well sampled. For those wells that had more than one complete analysis, the most recent complete analysis was used to generate the statistics.

DATA STATISTICS

Water from more than 25 percent of the wells sampled for lead contained concentrations greater than the detection limit of 10 $\mu\text{g/L}$. Included in this number are some wells that contained lead concentrations greater than the U.S. Environmental Protection Agency (USEPA, 1976) primary drinking-water regulation of 50 $\mu\text{g/L}$. Cadmium concentrations, although lower than lead concentrations, followed a similar pattern. In approximately 25 percent of the wells sampled for cadmium in the upper aquifer, the concentrations were at or greater than the detection limit of 1 $\mu\text{g/L}$.

Dissolved iron concentrations ranged from 5 $\mu\text{g/L}$ to 480,000 $\mu\text{g/L}$. More than 50 percent of the samples from each aquifer had iron concentrations in excess of the USEPA (1979) secondary drinking-water recommended limit of 300 $\mu\text{g/L}$.

The highest dissolved lead and dissolved iron concentrations, 130 and 480,000 $\mu\text{g/L}$, respectively, were measured in water from an unused well (25-208) in Keyport Borough. This well is screened in the upper aquifer. In water from the middle aquifer, the highest dissolved lead and dissolved iron concentrations were 130 and 240,000 $\mu\text{g/L}$, respectively, measured in water from well 23-371, an unused well in Sayreville Borough.

Chloride concentrations greater than the USEPA (1979) secondary drinking-water recommended limit of 250 mg/L were found in samples from wells in the cities of Perth Amboy and South Amboy, the boroughs of Keansburg, Sayreville, Keyport, and Union Beach, and the townships of Old Bridge and Woodbridge (table 5).

For the upper aquifer, the chloride values ranged from 1.2 to 2,500 mg/L. The higher value was reported in water from well 25-208 in Keyport Borough. For the middle aquifer, the chloride concentrations ranged from 1.0 to 5,500 mg/L; the higher value was reported in an observation well (23-1056) in Sayreville Borough.

Of the 21 samples collected from wells screened in the upper aquifer and analyzed for 30 volatile organic compounds, 5 samples contained at least 1 VOC at or above the detection limit. This number excludes well 23-31 (table 6). In the middle aquifer, 12 of the 21 samples collected and analyzed for VOCs contained at least 1 VOC greater than the detection limit.

Concentrations of pesticides generally were low. Of the 43 samples collected from wells screened in the upper aquifer and analyzed for pesticides, 4 samples contained concentrations of pesticides at or greater than the detection limit. In the middle aquifer, 6 of 38 samples collected and analyzed for 32 pesticides contained at least 1 pesticide with a concentration greater than the detection limit.

¹ Referenced to sea-level datum.

² Referenced to land-surface datum.

³ Aquifer units

ODBG Upper aquifer (Old Bridge aquifer), Potomac-Magothy-Raritan aquifer system
 FRNG Middle aquifer (Farrington aquifer), Potomac-Magothy-Raritan aquifer system

⁴ Use of site

O observation	W withdrawal
T test	Z destroyed
U unused	

⁵ Use of water

C commercial	P public supply
F fire protection	R recreation
H domestic	T institutional
I irrigation	U unused
N industrial	Z other

* Total well depth (screen setting unknown)

** Well has multiple screens

Table 4--Water-quality analyses of well-water samples, 1923-86

(Constituents not detected in a sample are reported as the value of
the detection limit for that analysis, preceded by a less than symbol(<).)

[°C, degree Celsius; mg/L, milligrams per liter; --, indicates sample not analyzed for this constituent]

NJ-WRD well number	Local well identifier	Date of sample	Tem- pera- ture Time (°C)	Spec- ific conduc- tance ¹	Oxy- gen, diss (mg/L)	Field pH (units)	Field al- kalinity (mg/L as (CaCO ₃)	Lab al- kalinity (mg/L as (CaCO ₃)	Field bicar- bonate ² (mg/L)	Solids, diss ³ (mg/L)

¹ Field specific conductance in microSiemens per centimeter at 25 °C.

² Computed field-bicarbonate concentrations may be higher than actual bicarbonate concentrations for water samples that have high concentrations of metals.

³ Dissolved solids, residue on evaporation at 180 °C.

⁴ Ammonia plus organic nitrogen, as N.

⁵ + Indicates at least one compound at or above the detection limit of 0.8 µg/L (micrograms per liter) for the VOC scan or 3.0 µg/L for the VOC analysis.

ND Indicates none detected.

-- Indicates sample not analyzed for these constituents.

Table 5.--Chloride concentrations and field measurements of well-water samples, 1923-86.

¹ Most specific conductances were measured in the laboratory prior to 1975, and in the field thereafter. Units are microsiemens/cm.

² On April 25, 1986, sample was collected from Well 25-420 after three days of continuous pumping for an aquifer test.

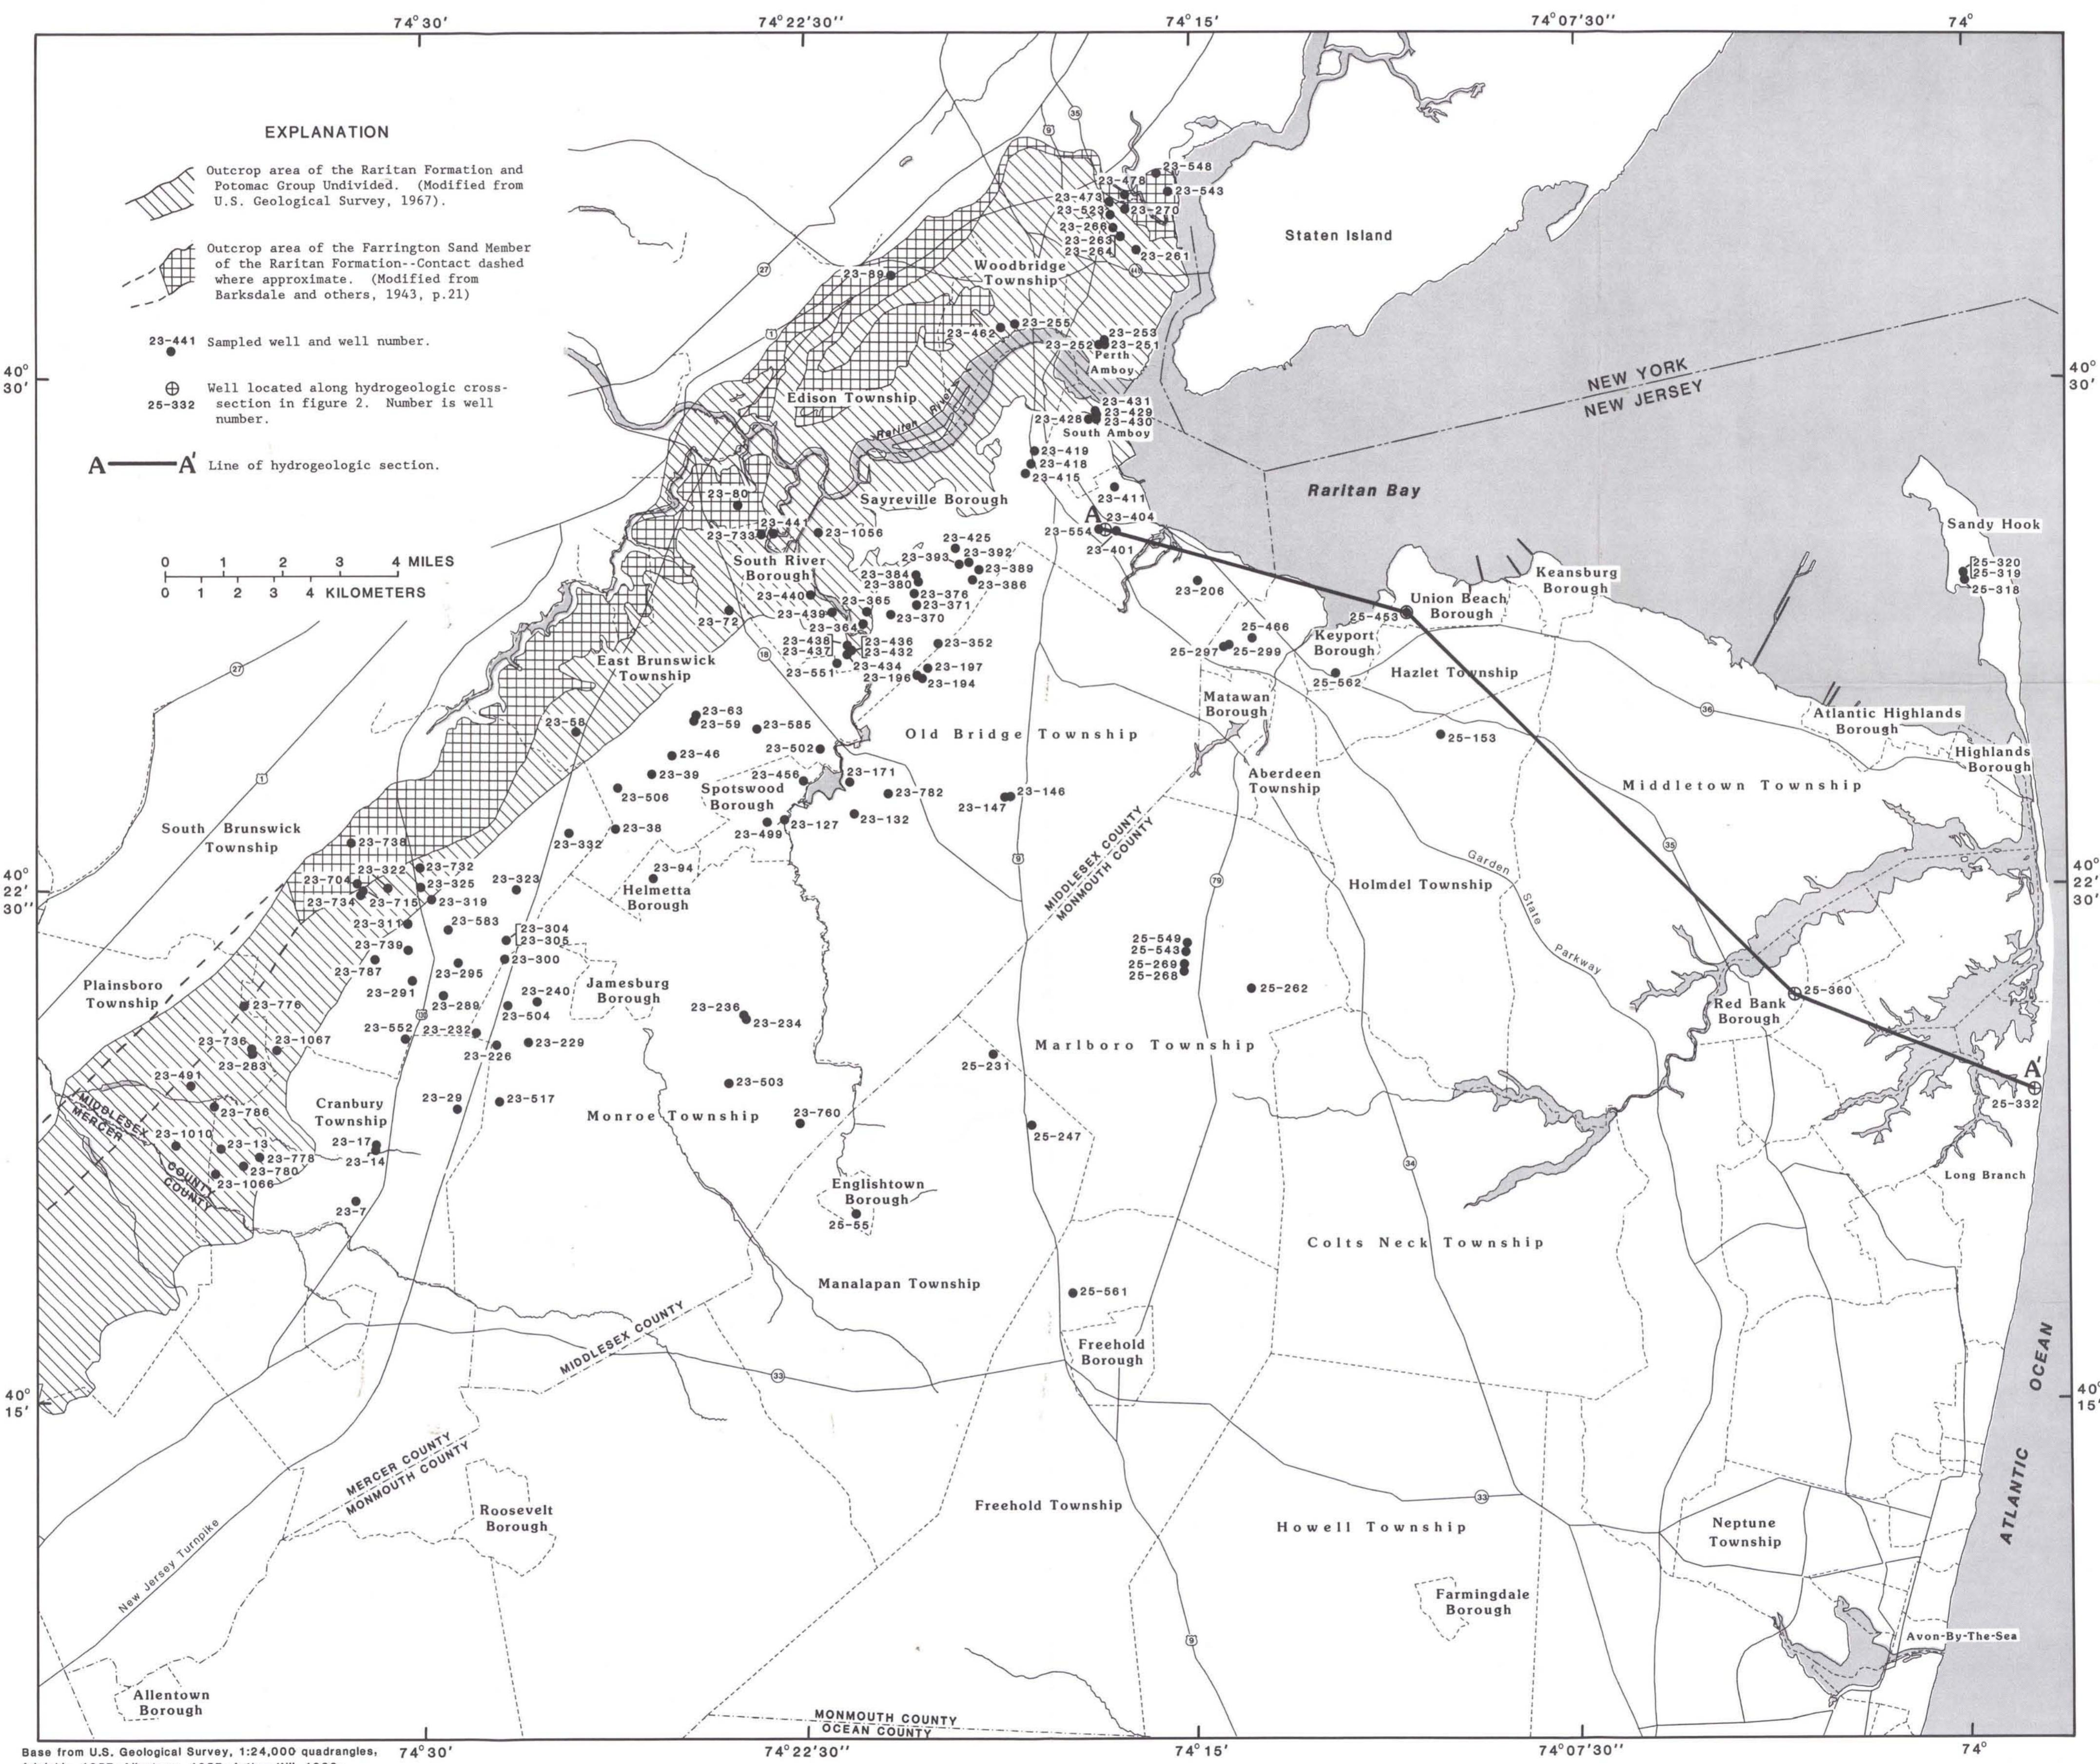

WATER-QUALITY DATA FOR THE POTOMAC-RARITAN-MAGOOTHY AQUIFER SYSTEM IN THE NORTHERN COASTAL PLAIN OF NEW JERSEY, 1923-86
(New Jersey Geological Survey Report 19)
