Public Service Electric and Gas Company Former Front Street Gas Works Newark, New Jersey

Remedial Investigation Report

March 1999

Prepared For:

Public Service Electric and Gas Company 80 Park Plaza Newark, NJ 07101

Prepared By:

Killam Associates A Subsidiary of Thermo TerraTech 27 Bleeker Street Millburn, NJ 07041

Project No. 263709

BEA000001

Exhibit "A"

CERTIFICATION

Pursuant to N.J.A.C. 7:26C-1.2(b)

Regarding the Remedial Investigation Report dated February 1999 for the Former Front Street Gas Works Site located in Newark, New Jersey:

"I certify, under penalty of law, that the information provided in this document is true, accurate and complete. I am aware that there are significant civil penalties for knowingly submitting false, inaccurate or incomplete information, and that I am committing a crime of the fourth degree if I make a written false statement that I do not believe to be true. I am also aware that, if I knowingly direct or authorize the violation of any statue, I am personally liable for the penalties."

#### **1.0 INTRODUCTION**

Public Service Electric & Gas Company (PSE&G) retained Thermo TerraTech (TerraTech) to perform a Remedial Investigation (RI) at a former manufactured gas plant (MGP) known as the Former Front Street Gas Works (Site). The Site is located on McCarter Highway in the City of Newark, New Jersey (Figure 1). The RI at the Site was performed as required by the Memorandum of Agreement (MOA) with the New Jersey Department of Environmental Protection (NJDEP) dated August 29, 1995. The RI was undertaken because of contamination found during the Site Screening Sampling Plan performed by Langan Engineering and Environmental Services, Inc. (Langan) in September 1997 as well as investigations performed by BCM Engineers (BCM), the United States Army Corps of Engineers (USACOE) and the New Jersey Department of Transportation (NJDOT).

The purpose of conducting the RI was to define the environmental impact on the subsurface from previous activities at the Site. In order to assess the environmental impacts, data gaps were identified and a scope of work was prepared to address those data gaps. The information was presented in the Remedial Investigation Workplan (RIWP) which was prepared by Woodward Clyde Consultants. The RIWP proposed:

- delineation of soil contamination;
- closure of the eight underground storage tanks (USTs) and investigation of the surrounding soils;
- investigation of the potential off-site transport of organic vapors in the subsurface;
- investigation of groundwater quality and aquifer characteristics.

The RIWP was approved by the NJDEP on March 11, 1998.

The RI field work was conducted between June and November 1998. All work was conducted in accordance with the approved RIWP, modifications to the RIWP memorialized in PSE&G's May

11, 1998 letter, the Technical Requirements for Site Remediation (NJAC 7:26E) and the NJDEP Field Sampling Procedures Manual (1992).

.

This Remedial Investigation Report (RIR) describes the activities and discusses the findings of the work conducted.

#### 2.0 BACKGROUND

#### 2.1 Site Location

The Site is located in the northeast part of New Jersey in the City of Newark in Essex County. The Site is comprised of two parcels of property separated by McCarter Highway (formerly Front Street) (Figure 2). Each of these parcels is described below.

- Parcel 1: Parcel 1 (Block 3, Lot 13 and Block 4, Lot 1 on the tax map of the City of Newark) encompasses an area of approximately 2.7 acres and is bordered by a restaurant to the north, the Passaic River to the east, a public parking facility to the south, and McCarter Highway (Route 21) to the west.
- Parcel 2: Parcel 2 (Block 14, Lot 28 on the tax map of the City of Newark) encompasses an area of approximately 0.23 acres and is bordered by Lombardy Street to the north, McCarter Highway to the east and public parking facilities to the south and west.

#### 2.2 Site Description

Parcel 1 is divided into two tiers separated by a driveway and a terrace. The upper tier (higher elevation) is located on the western portion, adjacent to McCarter Highway, while the lower tier is adjacent to the Passaic River. There are no existing above grade structures associated with the former MGP operations/support facilities. Below grade, there are active electrical lines along the western portion of Parcel 1 perpendicular to McCarter Highway and an active natural gas main running parallel to the property line between Parcel 1 and McCarter Highway. The utility locations are depicted on Figure 2.

Parcel 1 contains concrete and brick foundations of former buildings and gravel-covered and paved parking areas with a block retaining wall between the two tiers. Parcel 1 is enclosed by

fencing and is not accessible to the public. Former manufacturing facilities were limited to Parcel 1.

Parcel 2 contains an unpaved parking area. Parcel 2 is enclosed by a fence and is not accessible to the public. Parcel 2 contained only support facilities (e.g. offices, stables, etc.).

#### 2.3 Operating History

The operating history described below for the Site is based on maps and other information available in PSE&G files, previous reports for the Site (i.e. Preliminary Evaluation and Prioritization of 15 Manufactured Gas Plant Sites (BCM Engineers, February 1989)(which included reviews of Sanborn Fire Insurance Maps)), and aerial photographs. Based on the review of these documents, a chronological presentation of pertinent Site features and activities has been prepared and is presented below.

1868 Citizens Gas Light Company of Newark (Citizens) organized.

1869-1872 Parcel 1 (except for a small parcel along McCarter Highway) acquired by Citizens through a series of transactions. MGP operations may be presumed to have commenced sometime during this period.

1884 Remainder of Parcel 1 acquired by Citizens.

1891 Part of Parcel 2 acquired by Citizens.

1892 MGP equipment (including coal sheds, retort, iron tar tank, naphtha tank, and two iron gas holders) present on Parcel 1.

1895 Citizens merged with others to form Newark Gas Company.

Additional mergers occurred to form Newark Consolidated Gas Company.
 Newark Consolidated Gas Company leased its property, plant and franchises to the United Gas Improvement Company, which then leased these assets to the Essex and Hudson Gas Company.

- 1903 Remainder of Parcel 2 acquired. Wagon shed, stable, storeroom, meter repair shop, and carriage room located on Parcel 2. Site included in lease to Public Service Corporation of New Jersey.
- 1908 A third gas holder, an ammonia tank, and two tar tanks present on Parcel 1 in addition to other MGP equipment previously noted. Engine room constructed over the location of the iron tar tank. Naphtha and gas tanks now identified as oil tanks.
- 1909 Public Service Corporation assigns lease to Public Service Gas Company.
- 1924 Public Service Gas Company merges with Public Service Electric Company to form PSE&G.
- 1926 Site used as an auxiliary production facility.
- 1930 Site operating as a "reserve plant." An additional gas holder (#4) is present near the north property line. Retort house converted to a meter shop. Coal shed no longer used for coal storage, coal is now stored in stockpile near the southern property line.
- c. 1937 MGP facilities withdrawn from service. Removal of MGP facilities initiated from the Site. Site continues to serve as a holder station. Purifying house converted to storage/garage.
- Holder #1 and the three oil tanks adjacent to the purifying house removed.
  Holders No. 2 and 3 and building present.
- 1950s Holder station facilities removed from the Site.

.

- c. 1960 Site used as a district operations headquarters for gas department service and street operations.
- 1973 Parcel 1: Storeroom and garage shown at locations of former purifying house and meter room. Parcel 1 also has vehicle parking areas. A "10-inch artesian well" is shown at the southern property line near the Passaic River. Five USTs (2-4,000 gallon gasoline, 2-550 gallon gasoline, and 1-550 gallon "white gas" tank) and two pump islands located on Parcel 1.

Parcel 2: Offices and parking lot located on Parcel 2.

| 1977         | Two additional USTs installed (1-6,000 gallon unleaded gasoline, and 1-2,000      |
|--------------|-----------------------------------------------------------------------------------|
|              | gallon unleaded gasoline).                                                        |
| 1978         | One additional UST installed (6,000 gallon unleaded gasoline).                    |
| 1980         | Retort house, generator house, and boiler house structures removed from the Site. |
| 1995         | District Headquarters relocated and MOA filed with NJDEP.                         |
| 1 <b>997</b> | Parcels 1 and 2 vacant with no above ground structures.                           |

According to available information, the Site utilized the coal gas process, water gas process and carbureted water gas process. The coal gas manufacturing process involved the thermal reduction of coal in retorts. Processes common to coal gas manufacturing included coal charging, thermal reduction of coal, gas generation, condensing, cooling, gas cleanup and storage.

The water gas manufacturing process involved passing steam over and through an incandescent bed of hot coke, coal or other carbonaceous material. The manufacturing equipment consisted of a generator, waste heat boiler, and a wash box. The generator contained the coke bed; the waste heat boiler was used to extract heat from the gas produced or from the products of combustion when heating the coke bed; and, the wash box was used to cleanup the gas of all condensables.

The carbureted water gas manufacturing process was the water gas process enriched with a thermally cracked hydrocarbon such as oil. The manufacturing equipment consisted of a generator, carburetor, superheater, waste heat boiler, and wash box. The generator contained the coke bed used for generating the water gas and providing heat to the carburetor and superheater. The carburetor was where the hydrocarbon was added, usually vaporizing and being thermally cracked on checker brick installed in the carburetor. The superheater, also filled with checker brick, was where the thermally cracked hydrocarbon was reformed into methane, ethane, and other gaseous hydrocarbons.

#### 2.4 Physical Setting

#### 2.4.1 Land Use Assessment

Parcel 1 lies within the Second Industrial District (I-2). The principle permitted uses within I-2 are residential, commercial, business or light industry. Parcel 2 lies within the Fourth Business District (B-4). The permitted uses within B-4 are residential, retail sales, office, or business use. These zoning classifications may be re-designated in the future as a result of redevelopment efforts in the area.

The State of New Jersey, the City of Newark, and certain private developers are currently investigating a redevelopment of the area in and around the Site as part of a redevelopment of the Passaic River waterfront. The waterfront redevelopment project (known as the Joseph G. Minish Passaic River Waterfront Park and Historic Area) includes plans prepared by the USACOE New York District for the installation of sheet piling and the construction of a new bulkhead along the riverbank on the east side of Parcel 1. NJDOT also has plans to widen McCarter Highway. The widening includes the acquisition of a 50-foot wide strip of land traversing the western border of Parcel 1.

#### 2.4.2 Topography and Site Drainage

Parcel 1 consists of two topographical tiers separated by steep slopes and retaining walls. The average elevation of the upper tier along McCarter Highway is 38 feet above mean sea level (MSL). The average elevation of the lower tier along the Passaic River is 10 feet above MSL. Because most of the Parcel is capped (foundations and pavement) surface water infiltration is suspected to be low. Surface water runoff from Parcel 1 drains into the Passaic River.

Parcel 2 is relatively flat with an average elevation of 40 feet above MSL. Surface water runoff from Parcel 2 flows into storm sewers along McCarter Highway. The storm sewer system in this

area of Newark is reportedly combined with the sanitary sewer system with discharge to the Passaic Valley Sewerage Commission (PVSC) treatment facility.

#### 2.4.3 Wetlands/Surface Waters

According to the National Wetlands Inventory (NWI), the Site is categorized as upland. The Passaic River is classified as "estuarine - open water/unknown bottom." There are no other inventoried wetlands or other surface water bodies within 1,000 feet of the Site.

The Passaic River flows from north to south with tidal flow in the area of the Site. Approximately 4.5 miles downstream of the Site, the Passaic River flows into Newark Bay. The Passaic River is classified as "SE3" in the area of the Site. "SE" is the general surface water classification applied to saline waters of estuaries. The following uses are designated for SE3 surface water bodies: secondary contact recreation; maintenance and migration of fish populations; migration of diadromous fish; maintenance of wildlife; and any other reasonable uses.

#### 2.4.4 Local Climate and Rainfall

The climate in Essex County is generally temperate. The average annual rainfall is approximately 44 inches. The mean annual temperature is 55 degrees Fahrenheit (°F) with a monthly mean low of 23 °F in January and a monthly mean high of 87 °F in July (Source: Office of the New Jersey State Climatologist, 1997).

#### 2.5 Geologic Setting

#### 2.5.1 Regional Geology

The Site is located in a geologically complex area. It is located in the Newark Basin physiographic province, a northwestward-dipping wedge of faulted and folded sedimentary rocks punctuated by flood basalts of late Triassic and early Jurassic age, intruded by diabase dikes, sills, and laccoliths. The rocks of the Brunswick Group constitute the stratigraphically highest geologic unit in the Newark Basin. Geologic maps (Nichols, 1968; Lyttle and Epstein, 1987) indicate that the region of the Site is underlain at depth by consolidated strata of the Passaic Formation, the oldest unit of the Brunswick Group in New Jersey. The formation lithology consists of grayish-red to reddish-brown, thinly- to thickly-bedded shale, siltstone, sandstone, and conglomerate with subordinate cycles of gray and greenish-gray thinly-bedded shale and siltstone (Olsen, 1980; Van Houten, 1988).

These deposits were buried below later Mesozoic and Cenozoic coastal and marine deposits which were subsequently eroded away. During times of lower sea level than present, the terrain was deeply incised by streams. Some of these former stream valleys are as much as 300 feet below present sea level. The valleys are characterized by fluvial deposits that were subsequently buried by sediments related to cyclical glaciation.

The glaciogenic deposits, mapped by Stanford et al. (1990, 1995), consist of till to the west and glacial lake deposits at and to the east of the Site. The glacial lake deposits consist of lake bottom silts and clays, lacustrine fan and deltaic deposits, and minor ice-contact stratified deposits. In the area in the immediate vicinity of the Site, the map of Stanford et al. (1995) shows "deltaic/lacustrine fan deposits (sand and gravel)." The glacio-lacustrine deltaic deposit is approximately 2 square miles in area, extending to both sides of the Passaic River. The river has cut completely through the deltaic deposit and the portion on the west side of the Passaic River is no longer physically connected with the portion to the east. Immediately east of the bisected delta is an area mapped as glacial lake bottom deposits. These are rather extensive and represent much of the area of the extinct glacial Lake Hackensack, which covered parts of Bergen, Essex, Hudson, and Union Counties. There is a buried valley immediately east southeast of the Site.

The buried valley in the bedrock is part of a trough that runs parallel to the strike of the bedrock and marks the location of a pre-glacial stream valley. Sands and gravels are preserved in this valley beneath the overlying till plain of the Wisconsinan Glaciation. These coarse sediments constitute a buried valley aquifer that extends from Bergen County to the vicinity of Cranford, in Union County. Locally, the trough it occupies has been called the Kenilworth-Newark Valley (Nemickas, 1974). Nichols (1968) describes the buried valley deposits in "northern Newark, where the valley runs parallel to the Passaic River," as containing several deposits of sand and gravel interbedded with clay and till. The sand and gravel deposits are described as ranging from 1 to 19 feet thick and being "encountered mostly at depths of less than 50 feet and depths of more than 220 feet below land surface."

Where the glacial deposits are eroded by the Passaic River, they are partly covered by estuarine deposits consisting mainly of silty clays.

#### 2.5.2 Site Geology

The bedrock beneath the Site, is a siltstone characterized by interbedded friable (highpermeability) and blocky (low-permeability) layers that strikes approximately 28 degrees east of north and dips toward the northwest at an angle of approximately 8 degrees. In the vicinity of the Site, the bedrock is approximately 10 to 30 feet below MSL. Figure 3 depicts the topography of the top of the bedrock on-site.

The overburden on the Site is consistent with what one would expect with glacial depositional processes. The interpretation is based on drilling logs provided in Appendix A. There are 12 to 20 feet of fill material below which are native deposits. The upper tier (deltaic depositional environment) is marked by deltaic deposits 20 feet thick. Although no sedimentary structures were identified in the split spoon samples, these deposits, being primarily clean, silty, or gravelly fine- to medium-grained sands, are interpreted to be delta forset beds. A basal deposit of silt (with trace-to-some clay), approximately 4 to 6 feet thick, is present beneath the coarser

forset beds and is interpreted as a pro-deltaic environment. Underlying this silt stratum are glacial till sediments composed of clay, silt, sand, and gravel, which directly overlie the bedrock.

The lower tier, representing fluvial and estuarine depositional environments, is characterized by a 4- to 8-foot thick gray slightly organic clay underlying fill material. This clay was probably deposited as the result of flocculation of clay minerals upon reaching the brackish estuarine environment of the lowermost Passaic River. Underlying this clay are occasional fluvial sand and gravel deposits ranging in thickness between 2 and 4 feet. Since the Passaic River has truncated the earlier deltaic deposits, the estuarine clays are deposited directly on till in the southeastern portion of the lower tier, adjacent to the river. Further to the west, the pre-existing deltaic deposits are not completely eroded, and the estuarine clays on-lap directly upon the pro-delta silts exposed by erosion of the overlying fine-to-medium sands. Lithologic cross sections have been included as Figures 4, 5, and 6 which graphically depict subsurface conditions.

#### 2.6 Hydrogeologic Setting

. -

Regional groundwater flow discharges into the Passaic River, the Second River, Newark Bay, the Elizabeth River, and the drainage system around Newark Airport (which is the approximate location of the former Bound River). There is downward leakage through glacial deposits and exposed bedrock.

There appear to be two distinct water-bearing zones in the overburden soils beneath Parcel 1. Shallow groundwater, referred to as the "A" Horizon, occurs above the pro-delta silt and the estuarine clay, which together form a semi-confining layer which extends across the Site and probably continues an indefinite distance off-site. This semi-confining layer continues underneath the Passaic River. The deeper water-bearing zone referred to as the "B" Horizon occurs beneath the confining layer. There does not appear to be a confining unit separating this unit from the underlying bedrock. Consequently, the "B" Horizon and the bedrock are considered a single aquifer unit. This conclusion is supported by the presence of free product in the bedrock.

Synoptic groundwater elevations were measured on September 16, 1998 as part of the groundwater sampling episode. These data, presented on Table 1, indicate a flow toward the Passaic River. From previous investigations, it is known that both the "A" and "B" Horizons are influenced by the tidal fluctuations of the Passaic River. To evaluate the response of the hydraulic gradient to tidal fluctuations, water levels in seven wells (MW-2, MW-2A, MW-3, MW-3A, MW-3BR, P-2, and P-2A as shown on Figure 2) and the river were continuously recorded between October 14 and 17, 1998 by automatic data loggers equipped with pressure transducers. As indicated on Figure A of Appendix B, the water levels in all of the monitored wells, except P-2, exhibit a clear response to tidal fluctuations. Additionally, MW-3A exhibits a response to another external factor, possibly off-site pumping (e.g. basement dewatering via sump pump), which causes the tidal fluctuation curve to be erratic, rather than smooth but does not affect the overall groundwater flow. Tidal monitoring illustrated that the strongest responses to tidal fluctuations were found in the wells adjacent to the river and at the semi-confined wells in the Upper Tier, as would be expected.

The data from monitoring wells P-2, P-2A, MW-2, and MW-3 (located at respective corners of a tetrahedron) were evaluated to understand the horizontal and vertical gradient and determine the tidal effects on magnitude and direction of hydraulic gradient. The water level elevations from these wells were evaluated to calculate an azimuth bearing (degrees clockwise from north) and an angle of plunge (degrees downward from horizontal) for each hour in the period of data collection. These data were then used as input in a stereonet program (RockWare®) to calculate descriptive statistics for the azimuth and the angle of plunge of the hydraulic gradient utilizing a Schmidt projection. As indicated on Figure B of Appendix B, the results of this evaluation demonstrate that the mean direction of the hydraulic gradient is 71.5° east of north, with a downward mean plunge of 81.8° from the horizontal. The spherical variance was only 0.0001, indicating that direction of the hydraulic gradient is little affected by the tidal fluctuation during

the period of the measurements. Therefore, mean flow at the Site is always toward the Passaic River and the downward component of the hydraulic gradient is predominant.

#### 2.7 Receptor Evaluation

A well search was conducted as part of the 1989 Preliminary Site Investigation. A second well search was completed as part of this RI to update the results from 1989. Fourteen industrial and domestic wells were located by the well search (Table 2). The nearest wells are located at the intersection of Lombardy and Broad Street in the Bell Atlantic and Mutual Life buildings. Figure 7 shows the well locations and the well records are attached as Appendix C. There were no public supply wells discovered in the search. Since groundwater flows east toward to the Passaic River, these wells are not receptors.

The Passaic River is an ecological receptor. An ecological evaluation of the river, including the area adjacent to, upstream, and downstream of the Site, is being conducted by others at the direction of, and with oversight from, the USEPA.

Subsurface utilities have been discounted as potential receptors because they are at significantly higher elevations then the encountered contamination.

#### 3.0 PREVIOUS INVESTIGATIONS

Five environmental investigations have been conducted on or adjacent to the Site. These include a 1995 study by the USACOE for a streambank restoration project; a 1996 study by the USACOE for the Joseph G. Minish Passaic River Waterfront Park and Historic Area; a 1996/97 study by the NJDOT for the widening of McCarter Highway; a supplemental USACOE study; and a 1997 Site Screening performed by Langan for PSE&G. Results from these studies are summarized below. Figure 2 depicts boring locations from these previous investigations.

#### 3.1 USACOE Studies (1995/1996)

The purpose of the 1995 study by the USACOE was to determine the existence, nature and extent of hazardous and toxic materials within a construction project area along the west side of the Passaic River. The construction project included the repair of the bulkhead along the west side of the river, involving the excavation of soil and sediments.

The purpose of the 1996 study by the USACOE was similar to the 1995 study and would also provide planning data for an expanded project known as the "Joseph G. Minish Passaic River Waterfront Park and Historic Area." The expanded construction project includes construction of a public marina, scenic overlook, recreation facilities and a promenade. The promenade would cross the riverfront area of Parcel 1.

A detailed description of each boring was provided in the RIWP. The USACOE performed borings in the Passaic River at or near the Site and on shore. Findings revealed elevated concentrations of semi-volatile organic compounds (SVOCs), volatile organic compounds (VOCs) and metals. There was evidence of free product and/or black staining and strong petroleum hydrocarbon (PHC) odors present in the three borings (WT-10, WT-11 and WT-12) drilled in the Passaic River closest to the Site. The borings conducted on shore revealed the presence of free product and PHC odors.

#### 3.2 NJDOT Study (1996/97)

As part of the 1996/97 NJDOT study, seven soil borings (EB-32 through EB-36 and MEB-74 and MEB-75 as shown on Figure 2) were advanced along the western boundary of Parcel 1 near or in the locations of former Gas Holders No. 1, 2 and 3. These borings were drilled to depths ranging from 10 to 18 ft below ground surface (bgs). The boring logs indicate fill (including coal, concrete, brick and asphalt fragments), sand, gravel, and shale and siltstone fragments. Photoionization detector (PID) readings did not indicate organic vapor concentrations above background. Some black staining was noted. Chemical analyses of soil samples collected from these soil borings indicated exceedances of the most stringent NJDEP Soil Cleanup Criteria for polynuclear aromatic hydrocarbons (PAHs), beryllium, lead and thallium.

## 3.3 USACOE Supplemental Study (1997)

During September 1997, prior to implementation of the Site Screening, soil boring S-3 was advanced in the southeast corner of Parcel 1. This boring was drilled as part of a geotechnical study for the construction of a river bank bulkhead. This boring was observed and logged by Langan on behalf of PSE&G. Free product and/or organic odors were noted at different strata, including bedrock.

#### 3.4 Langan Site Screening Sampling (1997)

In order to gather sufficient data to develop the RIWP, PSE&G prepared and implemented a Site Screening Sampling Plan (Site Screening), to identify the general geology and environmental conditions. The 1997 Site Screening performed by Langan for PSE&G included fifteen soil borings, four pairs of shallow/deep piezometers (P-1/P-1A through P-4/P-4A), and five temporary well points (TWP-1 through TWP-5) along the Passaic River (Figure 2). Synoptic water level measurements were obtained, and the potential for tidal influences upon groundwater elevations was assessed. One round of groundwater samples was collected from the piezometers

and temporary well points and submitted for laboratory analysis. The fill/vent ports of five USTs were also investigated.

The Site Screening Program included a sample location plan, field observations of MGP residuals, boring logs, well construction summaries, NJDEP Forms A and B, groundwater elevation survey data, groundwater sampling field parameters, groundwater analytical results, and UST investigation results. The results were previously provided in Appendix D of the RIWP.

The soil borings identified the subsurface stratigraphy as well as a broad view of the environmental conditions under Parcel 1. The borings also were utilized to investigate some of the former MGP structures. The findings indicated that soil contamination would require more exhaustive investigation.

The groundwater investigation indicated that there were contaminant exceedances above and below a clay/silt layer and that groundwater was tidally influenced, but groundwater flow directions were not confirmed. The conclusion made from this portion of the investigation was that further delineation of groundwater contamination would be required.

#### 4.0 REMEDIAL INVESTIGATION - SOIL

As discussed in Section 3.0, previously conducted investigations have determined that soil contamination exists beneath Parcel 1 above and below the silt/clay layer. The presence of contaminated soil beneath the silt/clay layer warranted an investigation as to whether these contaminants have migrated into the underlying bedrock. The following sections will discuss the delineation of soil contamination, the extent of the silt/clay layer, and the impact of contamination on the bedrock. All work was conducted in accordance with the May 1992 NJDEP *Field Sampling Procedures Manual* (DEP-FSPM) and N.J.A.C. 7:26 E.

A soil investigation was undertaken to further characterize the soil contamination. Previous investigations conducted at the Site provided limited analytical information about the contaminants on-site. The information that was collected indicated exceedances of the Residential Direct Contact Soil Cleanup Criteria (RDCSCC) and the presence of free product. A grid of fourteen soil borings (B-11 through B-24) and nineteen test trenches was proposed for contamination delineation. The borings were biased toward former MGP structures and the perimeter of the Site, and the trenches biased to locate former MGP structures. Based on the findings of the initial borings and test trenches, additional borings (B-25 through B-48) were added to assist in the horizontal and vertical delineation of soil contamination. Boring locations are depicted on the Site Plan (Figure 2), test trenches are located on Figure 8 and boring logs are provided in Appendix A.

Soil borings were installed by Advanced Drilling Inc., of Washington, New Jersey, utilizing hollow stem auger and mud rotary drilling techniques. Soil samples were collected from the borings by driving 2-inch diameter split spoons. Before each use, the split spoons were decontaminated in accordance with the Field Sampling Procedures Manual. If free product was observed immediately above the semi-confining silt or clay, the boring was stopped and steel casing was installed into the unit so that the product would not be mobilized into the "B" horizon.

4.1

. -

Upon completion, all borings were sealed with an 80/20 mix of portland cement and granulated bentonite.

Test trenches were installed by Creamer Environmental Inc. of Hackensack, New Jersey. The trenches were installed to investigate the subsurface conditions and locations of former MGP structures. There were no soil samples collected from the trenches.

Soil samples were collected from borings B-11 through B-23 and analyzed for volatile organic compounds plus a library search for up to ten tentatively identified compounds (VO+10) (EPA SW-846, GC/MS Method 8260B) utilizing the NJDEP methanol preservation sampling technique; semi-volatile organics plus a library search for up to twenty tentatively identified compounds (SVOC+20) (EPA SW-846, GC/MS Method 8270C); and the Target Analyte List (TAL) of metals including Cyanide (Cn) (EPA SW-846 Methods 6010B, 7471A, and 9012M). Samples were collected for laboratory analysis in accordance with the following guidelines:

- The first sample was collected from a discrete 6-inch interval within the 0-2 ft bgs depth interval to determine if the surface soils were contaminated at that location. Because most boring locations were in paved areas, the discrete sample was collected immediately below the pavement material.
- The second sample was collected from the 6-inch interval directly above the first encountered groundwater.
- The third sample was collected at the bottom of the boring from the 6-inch interval directly above the bedrock.

Additional soil samples were analyzed in the lower tier of Parcel 1 (borings B-11 through B-17) according to the following:

- The fourth sample was collected from the 6-inch interval with the highest PID reading between the first encountered groundwater (second lab sample) and the top of the clay unit, if the PID reading was greater than the PID reading of the second lab sample.
- A fifth sample was collected from the 6-inch interval with the highest PID reading below the clay, if the PID reading was greater than the PID reading of the third lab sample.

Additional soil samples were analyzed in the upper tier of Parcel 1 (borings B-18 through B-23) according to the following:

- A fourth sample was collected from the 6-inch interval with the highest PID reading between the surface soil (first lab sample) and the first encountered groundwater (second lab sample), if the PID reading was greater than the PID reading of the second lab sample
- A fifth sample was collected from the 6-inch interval with the highest PID reading between the first encountered groundwater (second lab sample) and the overburden/bedrock interface (third lab sample), if the PID reading was greater than the PID reading of the third lab sample.

There were some in-field modifications to this initial plan as discussed below. Boring B-24 was installed inside the wall of Gas Holder #3, but was sampled, to the extent possible, according to the above guidelines. Borings B-25 through B-48 were installed to further delineate the findings of the initial boring program. These additional borings were sampled with a bias to the detected contamination from the initial boring.

The RIWP proposed to treat Parcel 1 as one area of concern (AOC). However, based upon the results of the RI, it was decided to subdivide the Parcel into several different AOCs, as each has its own distinguishing environmental concerns. Following is a description of each AOC and its relationship to data gaps identified in the RIWP. AOCs for shallow soils (0 to 2 feet), "A" horizon, and "B" horizon soils are included on the Soil Contaminant Box Maps depicted as Figures 9a, 9b and 10, respectively. Contaminant concentrations which exceed the most

stringent NJDEP Soil Cleanup Criteria have also been depicted on these plans. A summary of the laboratory data collected from the soil borings has been included as Tables 3A, 3B and 3C, a laboratory summary is included as Appendix D and the NJDEP Electronic Deliverable diskettes are included in Appendix D. All boring logs have been included as Appendix A.

#### 4.1 Data Gap No. 1 - Delineation of Soil Contamination

As a result of the field work phase of the RI, the AOCs were identified and delineated. The AOCs are divided among the surface soils, defined as the interval from 0 to 2 feet below grade, the "A" horizon, defined as the interval below the surface soils and above the semi-confining unit, and the "B" horizon, defined as the interval including and below the semi-confining unit and above bedrock. The following section describes the AOC and the potential contaminant sources.

#### Shallow Soil Contamination

<u>AOC-S1</u> - This AOC, depicted on Figure 9A, encompasses a majority of Parcel 1 and is characterized by elevated PAH and metal soil contaminants in the surficial soils (0 to 2 feet). During trenching of TT-11A, which was installed to investigate subsurface conditions of Gas Holder #1, and TT-10, which was installed to investigate a tar seep along the retaining wall, a tar-like product was observed seeping from immediately below the asphalt. The boundaries of this AOC are defined by retaining walls which exist along the northern and southern property lines.

<u>AOC-S2</u> - This AOC is depicted on Figure 9A as encompassing a small area in the southwest corner of the Lower Tier. This AOC is visibly defined by cyanide contaminated soil that is teal in color. An analytical sample was collected from this area and confirmed cyanide above the most stringent DEP soil cleanup criteria.

#### "A" Horizon Soil Contamination

AOC-A1 - This AOC has been depicted on Figure 9B as encompassing a majority of the Lower Tier, and the northern portion of the Upper Tier. AOC-A1 is characterized by elevated soil contamination and NAPL from the surface soils down to the top of the semi-confining unit. The AOC was developed with the findings from borings B-7A, B-8, B-9, B-10, B-11, B-12, B-14, B-15, B-19, B-26, MW-2, MW-3, P-3, P-4, S-3, and test trenches TT-3, TT-5B, TT-8, and TT-14. The borings and associated contaminant exceedances utilized for the characterization of this AOC are depicted on Figure 9B.

During drilling activities the observed PID readings were predominantly 25 ppm or lower, although there were two readings of over 100 ppm (B-15 at 12 feet (155 ppm), and B-26 at 6 to 8 feet (120 ppm)). The soil contaminants present were predominantly SVOCs, with some concentrations of VOCs and metals. The product observed in the borings and in the test trenches had a distinctive MGP odor. The product was black with an oily texture.

The test trenches were installed to evaluate the subsurface conditions around former MGP structures. TT-3 was installed to investigate the conditions around a former tar tank. During excavation, MGP residuals were observed between 4 and 5 feet below grade inside the walls of the tank. TT-5B investigated a former tar separator and encountered MGP residuals outside the confines of the concrete vault at a depth of 4 feet. TT-8 investigated two former oil tanks and encountered residuals at approximately 7 feet below grade. TT-14 encountered MGP residuals from a former tar tank at a depth of approximately 2.5 feet.

Based upon knowledge of MGP operations historically, the source of the contamination present in AOC-A1 is likely related to storage, processing, and transportation of the tar during routine Site operations. A portion of this AOC is in an area scheduled for the construction of a river walk. For this reason, the subsurface soils may come into human contact during construction. AOC-A2 - This AOC has been depicted on Figure 9B as encompassing the southern portion of the Upper Tier, extending west across McCarter Highway into Parcel 2, and south into the adjacent property. The AOC was defined by the extent of either MGP residual product or soil contaminant concentrations from the first encountered groundwater to the top of the semiconfining unit above the most stringent NJDEP Soil Cleanup Criteria (SCC) Field observations and analytical data from borings B-21, B-23, B-27, B-28, B-30, B-31, B-33, B-35, B-36, B-38, and MW-1 were used to define this AOC. The horizontal extent of the AOC was delineated based on borings not displaying an MGP impact (B-16, B-20, B-22, B-40, B-39, B-37, B-41, B-42, B-46, and B-48). AOC-A2 is distinguishable from A1 by a heavier phase MGP product with generally lower PID readings in impacted areas. The borings and associated contaminant exceedances utilized for the characterization of this AOC are depicted on Figure 9B.

During drilling activities, the observed PID readings peaked as high as 3,779 ppm in soil collected from MW-1A and were significantly higher than those detected in AOC-A1. The soil contaminants present are predominantly SVOCs and VOCs. The product observed in the borings was determined to be of MGP origin and was observed to be approximately 4 to 5 feet thick. Based on its distinct odor, volatility and location, lighter phase drip oil is the suspected source. There were two drip legs associated with Gas Holder #3 and the reported operation of the drip oil pump formerly located in the southwest corner of Parcel 1 (exact location unknown). The drip leg to the southeast of the holder was discovered during UST removal activities and its location is presented on Figure 2. The drip leg to the southwest was not discovered during the RI, but the location was addressed by both borings and wells. This AOC contributes to the dissolved-phase groundwater contamination.

#### "B" Horizon Soil Contamination

AOC-B1 - This AOC has been depicted on Figure 10 as encompassing a majority of the Lower Tier. AOC-B1 was defined by the extent of either MGP residual product or soil contaminant concentrations above the most stringent NJDEP Soil Cleanup Criteria below the semi-confining

unit. Field observations and/or analytical data from borings B-11, B-15, MW-2A and P-4A were used to define this AOC. The horizontal extent of the AOC was based on borings not displaying a MGP impact (B-32, MW-5BR, B-17, B-22, B-20, B-16, MW-3, MW-3A, and MW-3BR). The borings and associated contaminant exceedances utilized for the characterization of this AOC are depicted on Figure 10.

During drilling activities, the observed PID readings were less than 2 ppm. The soil contaminants present were predominantly SVOCs, with a trace of benzene. The MGP residual observed in the borings was black with an oily texture and was observed to be as thick as 18 feet at boring B-12.

## 4.2 Data Gap No. 2 - Delineation of Clay Layer

As discussed in Section 2.5, there were two distinct depositional processes at work at this Site. The Upper Tier has been defined as a deltaic depositional environment, while the Lower Tier represents a fluvial depositional environment. As there were two distinct environments depositing these sediments, there are also two distinct fine-grained deposits. Underlying the Upper Tier and extending under a portion of the Lower Tier is a moderate brown silt deposit with varying amounts of clay. A wedge of brown clayey silt has also been identified encroaching from the north. An organic grey clay extends from the Passaic River to a position adjacent to the silty deposits of the Upper Tier (Figure 11 depicts these units). The stratigraphy is depicted graphically on lithologic cross sections presented as Figures 4, 5, and 6.

## 4.3 Data Gaps No. 3 and 17 - Investigation of Bedrock

The property which lies south of the Site formerly housed the Ballantine Brewery. The brewery used on-site wells for process water. In the early 1900s, Ballantine reported water pumped from on-site wells contained tar. Research (see Section 5.5) has failed to produce specific detail on these on-site wells except that the wells were generally installed several hundred feet into the

bedrock. The bedrock core samples from boring S-3 (southeast corner of Parcel 1 and adjacent to the former Ballantine Brewery) exhibited naphthalene odors and elevated PID readings that indicated the potential presence of contamination in the bedrock.

For these reasons, it was determined that the bedrock required further investigation. The RIWP objective was to determine fracture orientation, and to evaluate potential pathways for contaminant transport utilizing 10 feet of core sample. Four bedrock borings were proposed, however, only three were installed as an artesian well, unearthed during test trenching, was used in the investigation. The RIWP proposed to rock core 10 feet, however, the rock cores were extended further to look for free product and fracture zones.

Bedrock borings were installed by initially setting 6-inch diameter steel casing approximately 5 feet into competent bedrock. After the grout was allowed to set for at least 24 hours, rock coring was initiated using NX sized core barrels. All core samples collected were immediately screened with a PID for the presence of volatile vapors. Samples were visually inspected for the presence of MGP residuals or product sheens. The cores were described for rock type, fracture orientation, rock quality description (RQD), and degree of weathering.

The bedrock encountered during the RI was composed primarily of siltstone with minor interbedded sandstone. The primary fractures observed in the bedrock are bedding planes which appeared as horizontal fractures in the cores (the true dip of the bedrock in this area is approximately 8° to the northwest, which is difficult to observe in cores). Occasional inclined fractures were observed throughout the cores.

Following is a brief description of the findings from the three bedrock borings. Boring logs, including lithologic descriptions and PID readings, have been included as Appendix A.

<u>Boring - MW-3BR</u> - The boring for the installation of MW-3BR was installed in the southeast corner of the Lower Tier of Parcel 1. The core at this location was extended from 33 to 124 feet

bgs to include the significant fracture observed during a video log of the nearby artesian well (please refer to discussion of artesian well in Section 5.4). A zone of significant fracturing was observed from approximately 106 to 111.5 feet bgs which likely corresponds to the artesian well fracture.

MGP odors, sheens and some minor amounts of tar-like products were observed from 43 to 74 feet and again from 92.6 to 124 feet. When coring the length of 99 to 104 feet, product was observed in the drilling fluid exiting the bore hole.

Boring - MW-4BR - The boring for the installation of MW-4BR was installed near the southwest corner of the Lower Tier of Parcel 1. The core at this location extended from 37 to 62 feet bgs. The core was extended for 25 feet to evaluate potential MGP impact downdip of MW-3BR. MGP odors, sheens and some minor amounts of tar-like products were observed from 37 to 46 feet. There was no visual evidence of MGP impact beneath 46 feet.

Boring - MW-5BR - The boring for the installation of MW-5BR was installed near the northwest corner of the Lower Tier of Parcel 1. The core at this location extended from 47 to 72 feet. Coring was conducted for 25 feet to evaluate for MGP impacts. The bedrock in this location was well weathered and highly fractured for the entire 25 foot core. There were no MGP odors, sheens or product observed during the installation of this boring.

#### 5.0 REMEDIAL INVESTIGATION - GROUND WATER

As discussed in Section 3.0, previous investigations determined that groundwater contamination exists beneath Parcel 1. The investigations detected dissolved-phase groundwater contaminants above ("A" water horizon) and below ("B" water horizon) the semi-confining unit. The presence of contaminated groundwater warranted an investigation as to the lateral and vertical extent of the impact. The following sections discuss the delineation of groundwater contamination, the hydrogeologic nature of the affected aquifers, the Site conditions for natural attenuation, and the potential local receptors and sources for contamination. Aquifer modeling was also conducted and is described herein, but additional data is required to complete the model.

#### 5.1 Data Gap No. 4 - Delineation of Groundwater Contamination

The initial Site Screening, conducted by Langan in 1997, showed that the "A" water horizon in the Upper Tier of Parcel 1 contained concentrations of organic compounds (benzene, xylene, and naphthalene) and inorganic analytes above the NJDEP Class IIA Ground Water Quality Standards (GWQS). With the exception of benzene, these concentrations decreased in the "B" water horizon. For the Lower Tier of Parcel 1, groundwater in the "A" water horizon contained concentrations of organic compounds (benzene, ethylbenzene, xylene, acenaphthalene, naphthalene, pyrene, fluoranthene, and fluorene) and inorganic analytes. The concentrations generally decreased in the "B" water horizon except for benzene at P-3/P-3A, and ethylbenzene, xylene and naphthalene at P-4/P-4A.

Based on the findings of the Site Screening investigation, it was proposed to conduct additional investigations in an attempt to further delineate and characterize the dissolved phase contamination at the Site. The RI focused on the organic contaminants in groundwater that resulted from MGP contamination. Three "A" water horizon (MW-1, 2 and 3), three "B" water horizon (MW-1A, 2A and 3A) and four bedrock monitoring wells (MW-3BR, 4BR, 5BR and 6BR) were proposed in the RIWP. As discussed herein, four "A" water horizon (MW-1, 2, 3, and

6), three "B" water horizon (MW-1A, 2A, and 3A) and three bedrock monitoring wells (3BR, 4BR, 5BR) were actually installed in accordance with the DEP-FSPM, the RIWP, and the modification letter to the DEP dated June 1998. The overburden monitoring wells were installed in clusters in the northeast, southeast, and southwest corners of Parcel 1, and bedrock wells were installed in the southeast, southwest, and northwest corners of the Lower Tier of Parcel 1. The wells were installed and developed during the summer of 1998 by Advanced Drilling Inc. of Washington, New Jersey in accordance with NJDEP well construction protocols. All drilling logs and well certification forms A and B have been provided as Appendix A. All wells were surveyed by Keller and Kirkpatrick for elevation and location after installations were complete.

In the "A" water horizon the wells were screened from above the water table to near the top of the semi-confining unit. The "B" water horizon wells were screened from beneath the semi-confining unit to near the top of bedrock.

Groundwater elevations were measured on September 16, 1998 and October 14 through 17, 1998. Groundwater samples were collected in accordance with the RIWP on September 16 and 17, 1998. Depth to water ranged from 2.65 to 34.56 feet below the top of PVC in the monitoring wells. Groundwater samples were collected from all Site wells with the exception of P-4, which was impacted with free phase MGP product. Groundwater sampling was performed utilizing the EPA low-flow sampling technique. Samples were collected from either the highest conductive zone, or the mid-point between either top of water or top of screen (whichever was lower) and the bottom of the well. Samples were analyzed for VO+10, SVOC+20, metals, cyanide, total dissolved solids (TDS) and chlorides by Accutest Laboratories of Dayton, NJ (NJ Laboratory Certification No.12129). The results of the groundwater quality analyses are shown on Table 4; groundwater elevations and field chemistries are included as Table 1; a laboratory summary is included as Appendix E; NJDEP Electronic Deliverable diskettes attached in Appendix D; and groundwater sampling logs are included as Appendix F. The complete analytical data packages are not included in this report, however, they are on-file at PSE&G Headquarters in Newark, NJ. Based on data validation of the laboratory packages by JMR Associates and Valerie Smith, most

of the data is reliable. Data has been qualified with an "R" when it has been determined to be unreliable. Data validators performed a structured data review based on standard operating procedures from the NJDEP Division of Publicly Funded Site Remediation. Below is a general summary of the items that were evaluated. Method specific items were also evaluated to determine the validity of the data (e.g. Internal Standards for GC/MS analysis and ICP Interference Check Solutions for metals ICP analysis).

- The data package deliverables were evaluated for completeness as described in
   N.J.A.C. 7:26, Appendix A.
- Sample holding times were checked to ascertain the validity of the data.
- All tuning and calibration records were checked to determine that they meet method specific criteria.
- Method, trip and field blanks were evaluated to determine any field or lab contamination.
- Matrix spikes and duplicates were assessed to determine the precision and accuracy of a method using a specific matrix.
- Lab control samples and blank spikes were assessed to determine the laboratory's precision and accuracy for each method.
- Calculations were spot-checked when sufficient raw data was available.

BTEX (benzene, toluene, ethylbenzene, and xylene) isoconcentration contour maps (Figure 12A and 13A) and groundwater contour maps (Figure 12B and 13B) have been prepared for the "A" and "B" water horizons. A Groundwater Contaminant Box Map is included as Figure 14. These figures depict the contaminant plume both above and below the semi-confining unit. Groundwater flow direction, and known soil contaminated areas were considered for the construction of Figures 12A and 13A. More work is required to complete "A" horizon groundwater delineation to the east, northwest and south, and "B" horizon groundwater delineation in the bedrock was minimal, therefore an isoconcentration map is not presented.

# 5.2 Data Gap No. 5 - Aquifer Characteristic Testing

Aquifer permeability tests (slug tests) were performed between September 23 and 25, 1998 at sixteen monitoring wells to determine the hydraulic conductivity (K). The slug tests at the unconfined (MW-1, MW-2, MW-3, P-1, P-2, and P-3) and semi-confined wells (MW-1A, MW-2A, MW-3A, P-1A, P-2A, P-3A, and P-4A) were conducted by instantaneously removing approximately one gallon of water from each well using a bailer, and then measuring the rate of rise of the water level in the well. The slug tests at the bedrock wells (MW-3BR, MW-4BR, and MW-5BR) were conducted by instantaneously placing an enclosed, filled bailer into the well, and then measuring the rate of fall of the water level in the well. An automatic data logger, equipped with a down-hole pressure transducer, continuously recorded the changing water level until it attained an elevation corresponding to a recovery of greater than 90% of the removed/installed volume. Monitoring wells MW-6 and P-4 were not tested due to an insufficient volume of water and the presence of coal tar, respectively.

The test data were analyzed using the Bouwer and Rice method (Bouwer and Rice, 1976; Bouwer, 1989) for determining hydraulic conductivities of an unconfined or confined aquifer with partially or completely penetrating wells. The Bouwer and Rice method utilizes the saturated thickness of the aquifer (D), the depth of the well bottom below the static water level (H), and the length of the screened interval below the static water level (L), in addition to the semi-log slope of the recovery data, to calculate hydraulic conductivity. Since hydraulic conductivity is overwhelmingly influenced by the most permeable stratigraphic layer which intersects the saturated portion of the screened interval, the well boring logs were reviewed to determine the most permeable layer. The thickness of the most permeable layer, in relation to the well screen and static water level, was then utilized to calculate the parameters of D, H, and L. A summary of this evaluation and the hydraulic conductivity results are presented in Table 5. Graphs of the actual tests and more detailed computations are presented in Appendix B.

. -

Antecedent monitoring was performed at all monitoring well locations to evaluate the extent of any tidal influence at the time of the permeability testing. Several of the wells (MW-2, MW-2A, and MW-3) located immediately adjacent to the Passaic River were corrected for a background tidal influence. One monitoring well (P-3A) exhibited such a strong response to the tidal change that the corrected data continued to exhibit a curvilinear response which could not be analyzed. Other wells, known to exhibit tidal fluctuations, did not need to be corrected as the water level in the Passaic River was relatively steady (slack water) at the time of testing or the test data period did not exhibit any significant impact from tidal influence.

As indicated on Table 5, the analyses yielded values ranging from 0.36 ft/day (MW-3) to 144.3 ft/day (MW-2) in the unconfined wells, 0.15 ft/day (P-4A) to 45.9 ft/day (MW-3A) in the semiconfined wells, and 1.44 x  $10^{-2}$  ft/day (MW-5BR) to 15.3 ft/day (MW-3BR) in the bedrock wells. The geometric mean hydraulic conductivity value was 7.46 ft/day for the unconfined wells, 4.07 ft/day for the semi-confined wells, and 1.45 ft/day for the bedrock wells.

### 5.3 Data Gap No. 6 - Natural Attenuation Evaluation

The ASTM Remediation by Natural Attenuation (RNA) guide (ASTM, 1997) suggests that there are three lines of evidence to be explored in assessing natural attenuation at a site: 1) primary line of evidence (documented loss of contaminants from the site); 2) secondary line of evidence (geochemical indicators of naturally occurring degradation); and 3) tertiary line of evidence (optional data such as microbiological information and modeling of contaminant transport).

Table 6 summarizes groundwater sampling conducted at the Site to assess natural attenuation of the principal contaminants of concern (BTEX and naphthalene). In horizon "A", "clean" groundwater is found upgradient in MW-6. In the source area well (MW-1), BTEX levels are a high of 17.51 mg/l. In the downgradient well (MW-3), BTEX levels drop to 0.07 mg/l. Naphthalene also exhibits a decrease from 9.94 mg/l at MW-1 to non-detect at MW-3. Groundwater moving through horizon "B" collects 2.79 mg/l of BTEX in the source area (MW-

1A) and drops to non-detect at MW-3A. Similarly, naphthalene levels start at 1.04 mg/l at MW-1A and drop to 0.0017 mg/l in MW-3A. These reductions in contaminant levels represent a primary line of evidence of natural attenuation processes such as biodegradation, dispersion, dilution and adsorption.

The secondary line of evidence relates more directly to the effect of biodegradation on the plume. BTEX compounds constitute the primary food source for hydrocarbon-degrading bacteria, but naphthalene is degradable as well, and since it will represent a "demand" on available electron acceptors, will be included in this analysis. These compounds are subject to both aerobic and anaerobic processes. Indigeneous microbial communities will use a variety of electron acceptors in an effort to degrade available organic material. The sequence of electron-acceptor utilization is set by the amount of energy available from each process (called a Terminal Electron Acceptor Process, or TEAP). Since dissolved oxygen provides the most energy to the degrading bacteria, it is the preferred electron-acceptor. Once the available oxygen is consumed, other anaerobic bacteria will become better able to compete and will start to use the alternate electron acceptors. The sequence of TEAPs, as typically reported (Wiedemeier et al., 1995), involve oxygen, nitrate, ferrous iron and manganese (IV), sulfate and carbon dioxide.

The general trends observed at almost all degradable hydrocarbon contaminated sites are evident at the Site. Table 6 indicates that between the "clean" upgradient well (MW-6) and the source area well (MW-1) in horizon "A", the following changes occur:

| decreases fi |
|--------------|
| decreases fi |
| increases fr |
| incr         |
| decreases fi |
|              |

decreases from 4.6 mg/l to 0.43 mg/l decreases from 27.4 mg/l to ND increases from ND to 10.4 mg/l increases from 0.7 mg/l to 9.0 mg/l decreases from 98 mg/l to 66.3 mg/l

Each of these changes is consistent with the hypothesis of sequential aerobic/anaerobic biodegradation. The dissolved oxygen, nitrate and sulfate that are present in the upgradient

groundwater are used as electron acceptors (although sulfate is not completely utilized). Iron that is available as coatings of aquifer sediments is transformed from the oxidized state (Fe III) to the soluble, reduced state (Fe II), increasing iron levels in groundwater. Manganese reduction is also occurring and is included here even though that process is not always described in the literature on natural attenuation (since manganese is not as ubiquitous as iron). The final process in the sequence, the reduction of carbon dioxide producing methane (methanogenesis), was not assessed, but is likely occurring in the core of the plume.

It is possible to roughly quantify the amount of degradation attributable to each process. Table 7 uses the changes in electron acceptors or redox species (increased iron and manganese levels results from the transformation of oxidized species to reduced (more soluble) species) to calculate the expressed assimilative capacity (EAC) of each process. For example, studies indicate that approximately 3.14 mg/l of dissolved oxygen is utilized in the aerobic degradation of 1 mg/l of BTEX hydrocarbon. Similar utilization factors have been developed for each TEAP (Rifai et al., 1998), and those values are used in Table 7 to assess the amount of hydrocarbons that can be degraded by the aquifer. The sum of all EACs is 14.94 mg/l, which is similar in range to the highest BTEX concentration encountered at the Site (17.51 mg/l). Adding naphthalene (9.94 mg/l in MW-1) to the list of degradable hydrocarbons raises the total to 27.45 mg/l, compared to the EAC of 14.94 mg/l. Still, this suggests that the aquifer has the capacity to constrain the plume to some finite distance from the source area since electron acceptors are inputted into the plume along its entire perimeter. Given that upgradient well MW-6 is screened only in horizon "A", it is not possible to apply a similar analysis to horizon "B." Table 6 indicates that the source well (MW-1A) contains little iron or manganese, suggesting these TEAPs are not significant. Dissolved oxygen and nitrate are very low, suggesting those processes may be active. Sulfate levels are inconclusive.

Other indicators which point to biodegradation in horizon "A" include the change in pH, alkalinity and temperature in the source area relative to upgradient. Each of the TEAPs described produces  $CO_2$  as an end product (even methanogenesis). This accumulation of  $CO_2$ 

5.7

typically depresses pH and, in aquifers with carbonate minerals as part of the matrix, increases alkalinity. Also, the increased microbial activity in a source zone compared to upgradient would result in a slight increase in temperature between the two areas.

### 5.4 Data Gap No. 7 - Historic Artesian Well Investigation

The 1973 revision of the property plan showed an artesian well located along the southern property line in the Lower Tier. The well was not referenced in the Well Permit Inventory presented in the 1989 Preliminary Site Assessment, therefore, its presence and status were evaluated during the RI.

Advanced Geological Services performed a ground penetrating radar (GPR) survey on June 2, 1998 to locate the artesian well. GPR identified an area for excavation, and upon excavation, the well was found in an open top concrete vault with a steel plate covering the top. The well was approximately 165 feet deep and 10 inches in diameter.

It was decided to utilize this well in place of a fourth bedrock well. Advanced Drilling subcontracted William Stothoff Drilling Co. to perform a down hole video taping of the well for delineation of fractures and bedrock description. The initial video quality was poor due to a large amount of debris that obscured the view of the bedrock. The well exhibited what appeared to be a weathered bedding plane or fracture from 106 to 109 feet below grade. Other minor fractures or bedding planes were identified and their locations were recorded. A second attempt was made to video the well after the casing was scrubbed and the well purged of one volume of water. The second video was still of poor quality.

It was decided to sample the water quality in the artesian well in an attempt to delineate the vertical distribution of dissolved contaminants in the bedrock aquifer. Samples were collected at 45 feet (beneath the steel casing), 107 feet (the middle of the weathered zone), and 145 feet (near bottom of well). Samples were collected utilizing the EPA low-flow sampling technique.

Samples were analyzed for VO+10, SVOC+20, metals, TDS, and chlorides. Sample results have been summarized on Table 4. Results depict fairly uniform contaminant concentrations across these three zones of detected parameters. Uniformity was also observed in the temperature log (Appendix E) where the water temperature did not vary more than 0.6 °C.

The well was abandoned by tremie grouting with an 80/20 grout/bentonite mixture on October 22, 1998. A well abandonment report is included in Appendix A.

### 5.5 Data Gap No. 8 - Well Search

A well search was conducted as part of the 1989 Preliminary Site Investigation. A second well search was conducted during the RI to update the results from 1989. This well search consisted of reviewing the NJDEP's and the City of Newark's well records. The well search did not provide any information regarding the former Ballantine Brewery wells. Fourteen industrial and domestic wells were identified by the well search. The nearest wells are located at the intersection of Lombardy and Broad Street in the Bell Atlantic and Mutual Life buildings approximately 500 feet west and upgradient of the Site. There were no public supply wells identified in the search. The on-site groundwater flow was consistently toward the Passaic River, therefore, the industrial and domestic wells are not potential receptors (see Section 2.7). Figure 7 depicts the well locations and the well records have been summarized on Table 2 and attached as Appendix C.

## 5.6 Data Gap No. 9 - Records Review

An Electronic File Search was obtained from Environmental Data Resources (EDR) which utilized the federal and state Environmental Record Sources stipulated by American Society of Testing and Materials (ASTM). It was requested that EDR map any site located within the minimum search distance required for a respective federal and state Environmental Record Source. EDR's report has been included in Appendix G. A list of the federal and state Standard Environmental Record Sources reviewed and applicable approximate minimum search distances are presented below.

| Source                                                                                                                              | Date           | Search<br>Distance |
|-------------------------------------------------------------------------------------------------------------------------------------|----------------|--------------------|

For the purposes of this report, adjoining properties are defined as any real property or properties that are contiguous or partially contiguous with that of the subject property, or would be contiguous or partially contiguous with that of the subject property but for a street, road, or other public thoroughfare separating them.

. 2

A review of the data received during this investigation revealed no likely off-site sources for the contamination present at the Site. For a detailed description of the file review, please refer to Appendix G.

MW-6 was installed in Parcel 2 to serve as an upgradient monitoring point to determine whether an upgradient source may be contributing to the dissolved phase contamination on-site. Samples collected from this well revealed only minor dissolved metal contamination above NJDEP GWQS. Soil samples (B36, 37, 38, 39, and 41) were also collected from Parcel 2 and reveal MGP residual product along the eastern property line but not further west. These data indicate that an upgradient off-site source is not suspected in contributing to the on-site contamination of the overburden.

### 5.7 Data Gap No. 10 - Aquifer Modeling

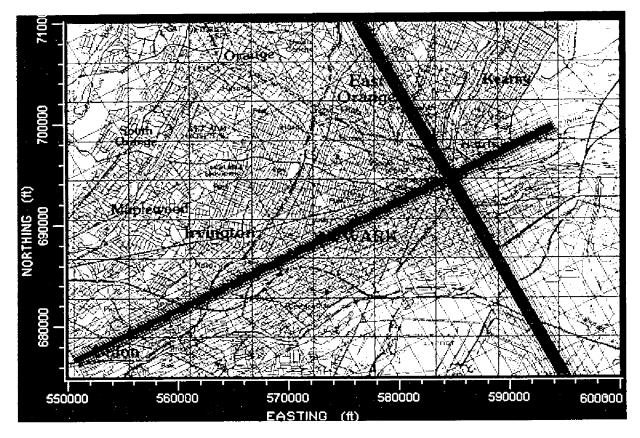

Aquifer modeling was performed to predict the hydraulic impact of the construction of an impermeable retaining wall, consisting of sheet piling, along the Passaic River adjacent to the Site. Toward this purpose, an aquifer hydraulic simulation was created. The model simulates the recharge, aquifer hydraulics, and discharge in the vicinity of the Site. It takes into consideration the regional stratigraphy, the structure of the bedrock and the overburden deposits, and the results of on-site hydraulic conductivity testing and water level measurements. The model is a steady-state simulation of the present Site conditions and was calibrated against present head conditions. The simulation was used to determine flows through the overburden and upper bedrock and to the Passaic River as exist currently and was used to predict changes in groundwater elevations in wells, hydraulic gradient, and groundwater flow direction in response to the hydraulic barrier to be introduced when the wall is constructed as part of the waterfront development.

5.11

### 5.7.1 Hydrogeological Framework

The Site and the surrounding region were modeled utilizing Visual Modflow ® (version 2.60), a three-dimensional graphical groundwater flow program, based upon the U.S.G.S. modular three-dimensional aquifer simulation package MODFLOW (McDonald and Harbaugh, 1988). The structure of the model consisted of a discretized grid with 94 columns, 88 rows, and 4 layers. A plan view is shown in the text figure below. The model grid was rotated 28° west of north so that flow would be modeled parallel to the proposed barrier in the vicinity of the Site. Within the confines of the model boundaries lie the Passaic River to the east, the drainage system of Newark Airport and the Arthur Kill to the South, the Elizabeth River to the west, and the Second River to the north. These features provided natural hydrogeologic boundaries in relation to the Site.

The water elevations at the hydrogeologic boundaries were determined utilizing a U.S.G.S.

topographic map of the pertinent area. Those features at sea level (e.g., the Passaic River south of Kearny, the Newark Airport drainage system, and the Arthur Kill) were modeled as constant heads with elevations of 0 feet above mean sea level (ft MSL). The other rivers were set as drains with general heads representative of those indicated on the topographic maps and with a streambed conductance of 1,000 ft/day. All hydrogeologic boundaries (constant heads and drains) were modeled in Layers 1, 2 and 3. These water bodies were not considered to bisect the bedrock or the buried valley aquifer (Layer 4).

The grid was discretized to provide high resolution in the vicinity of the Site and progressively expanded off-site, providing less resolution away from the area of concern. In the Site area, the four model layers simulated the varying hydrogeology. The unconfined layer (Layer 1) representing the "A" Horizon was divided into two zones (deltaic and fill) based on stratigraphic information summarized in the well and boring logs. The deltaic zone was predominantly on the western portion of the Site while the fill zone was predominantly on the eastern portion of the Site while the fill zone was predominantly on the eastern portion of the Site and the gray clay predominantly on the eastern portion of the Site, towards the river. The "B" Horizon (Layer 3) was consistent throughout the Site as was the bedrock layer (Layer 4). Outside of the Site, the parameters for each layer were modified. Since the glacial till is the predominant overburden material throughout the region, the off-site areas of Layers 1, 2, and 3, away from the area of concern, were modeled utilizing till parameters. In addition, to the south, the model contained a second zone in Layers 3 and 4 to represent a greater till thickness and the presence of the buried valley aquifer system, respectively.

At the Site, the geologic logs were evaluated to determine the bottom elevations of Layers 1, 2, and 3, as described above, and the layer bottoms were created using these elevations. Away from the Site, the bottom elevations of Layers 1, 2, and 3 were modeled as constants, based on boring log observations at the borders of the Site as well as in response to regional changes. The bottom of the bedrock layer (Layer 4) was consistent across the model.

5.13

### 5.7.2 Local Recharge

An estimate of regional recharge was obtained using a modification of the method presented in Charles *et al.* (1993). The method uses land use/land cover (LULC) overlays, which make use of up to 13 LULC codes to divide the region of interest into constituent areas. These overlays are constructed for the area or municipality under consideration and are then overlaid on an appropriately scaled soils map. This further divides the area of interest into numerous subregions, each with a specific soil type and LULC code. Charles *et al.* (1993) provides a set of "recharge factors" and "recharge constants" for each possible combination of soil type and LULC code. The recharge factor is then multiplied by a "basin factor," which is always equal to 1.3, and a "climate factor," which is provided by Charles *et al.* (1993) for each municipality in New Jersey. The recharge constant for each subregion is then subtracted from the product of these factors to obtain the recharge rate, in inches per year. Multiplying the recharge rate by the area of the subregion would allow an estimate of the value of the subregion as a recharge area.

The land use in the upgradient portions of the modeled area is primarily residential. The lot sizes are rather small. Consequently, the Charles *et al.* (1993) LULC designation of 1, "Residential (65% impervious), 1/8 acre lots - usually multi-family dwelling units," was used for a general estimate of the regional recharge.

There are no published NRCS Soil Surveys for Essex and Hudson Counties. Since the method makes use of NRCS Soil Survey soil designations, a modification of this method was necessary. The modification employed here is simply to consider the main soil types present in the closest sections of neighboring Union and Bergen Counties, for which soil surveys are available. The adjacent regions in these counties are geologically comparable to the Essex County areas included within the aquifer model. It was reasoned that if the soils were the same on either side of area of interest, we could have some assurance that the modeled soils would be the same. Except for the designation "urban land, " which could represent any pre-existing soil type, more than 90 percent of the area in the closest portions of Bergen and Union counties is covered by

Boonton soils. The remainder are Dunellen Soils or surface water. Charles *et al.* (1993) treats all the soils within a soil unit as hydraulically equivalent. Consequently, the recharge factors and recharge constants are the same for all the soil groups within the Boonton unit, regardless of whether they are "stony silt loams, 8-15 percent slopes" or "very stony silt loams, 15-30 percent slopes."

Boonton soils, with an LULC code of 1, are assigned a Recharge Factor of 4.70 and a Recharge Constant of 2.62. The climate factors for Newark, Belleville, East Orange, Irvington, Hillside, and Elizabeth are 1.31, 1.44, 1.39, 1.31, 1.31, and 1.31, respectively. The average is approximately 1.34. Applying the recharge formula of Charles *et al.* (1993) to this loosely defined area yields an annual recharge rate of 5.57 inches per year (=  $[1.3 \times 4.70 \times 1.34] - 2.62$ ). This was the general regional recharge rate applied across the modeled area.

# 5.7.3 Initial Values for Hydraulic Parameters

The geometric mean hydraulic conductivity values were utilized as initial values in the aquifer numerical model for the unconfined layer (7.46 ft/day), the semi-confined layer (4.07 ft/day), and the bedrock (1.45 ft/day). Hydraulic conductivity values for the clay/silt layer were obtained from triaxial permeability testing performed on collected Shelby tube samples. These triaxial permeability results are summarized on Table 5 and the data are presented in Appendix B. Since there were significant variations between computed hydraulic conductivity values among monitoring wells within the same layer, each geometric mean was not considered to be an explicit value for each layer, but rather a starting point in the numerical model. The final hydraulic conductivity values in the calibrated model varied from these starting values but remained within the range of test results. In addition, the triaxial permeability results were determined to be representative, but not definitive of the brown silt and gray clay. Final hydraulic conductivity values in the brown silt and gray clay in the calibrated model varied from these starting walues utilized in these starting values. Table 8 contains a summary of all hydraulic conductivity values utilized in the final, calibrated simulation.

### 5.7.4 Calibration

Synoptic water levels observed on October 14, 1998 at the on-site wells were used as calibration targets in the model. The water levels at the respective locations of each monitoring well were simulated. For each calibration run, these simulated heads were compared with the water level elevations measured in the field. The initial starting hydraulic parameters utilized in the model produced simulated water level elevations that (1) exceeded the target elevations in the "A" Horizon, (2) were similar to those observed in the "B" Horizon, and (3) were comparable to those in the bedrock. Based upon these initial results, different parameters were modified to calibrate the model and obtain a best-fit for the water levels in all three horizons. A plot of the calculated heads versus observed heads for the final calibration run is presented on Figure C included in Appendix B.

Originally, only one zone (fill/deltaic) was modeled in Layer 1 on-site. To better simulate the change in horizontal hydraulic gradient, it was determined that distinct transmissivity zones were required for the predominantly fill portion of the Site and the predominantly deltaic portion of the Site, as discussed in Section 2.5. The hydraulic parameters for these two zones were based on the hydraulic testing results performed at wells that were located in these two areas. The two zones in Layer 2 underwent only slight modification. It was determined that the horizontal and vertical hydraulic conductivities of the brown silt were greater in relation to the gray clay than originally modeled. The final values for the brown silt and the gray clay are in agreement with literature values. There were no changes to the hydraulic parameters in Layer 3 except in the area of the buried valley aquifer. It was determined that the thickness of the till overlying the buried valley aquifer was substantially thicker than in other parts of the region. Therefore, the horizontal hydraulic conductivity (K<sub>h</sub>) was increased and the vertical hydraulic conductivity (K<sub>v</sub>) was decreased to simulate this greater thickness. The hydraulic parameters in Layer 4 were only slightly modified from starting values (i.e., original  $K_h = 1.45$  ft/day, original  $K_v = .145$  ft/day; final  $K_h = 2$  ft/day, final  $K_v = .2$  ft/day) away from the buried valley aquifer. At the buried valley aquifer, there were no changes to the hydraulic parameters. Initial values of recharge, constant

heads, and drain elevations and conductances were not modified during calibration.

The simulated hydraulic gradients were well matched to the observed gradients in the "A" Horizon in terms of magnitude and direction. While the magnitude of the simulated hydraulic gradient in the "B" Horizon was similar to the observed, the simulated direction was the same as that of the "A" Horizon. As discussed earlier (Section 2.6), the observed hydraulic gradient in the "B" Horizon is directed somewhat more to the north on Site than that of the "A" Horizon. This is probably the result of a major bedrock fracture in the vicinity of MW-2A that resulted in a bedrock channel in that area (Figure 3). Since the most likely discharges for the bedrock aquifer are the Passaic River and the buried valley aquifer, which are to the east and south of the Site, respectively, it is assumed that the northeastward component in the "B" Horizon on the Site is regional. Consequently, we did not attempt to match it in calibration. The effect of not considering this deviation is to perhaps overestimate the amount of flow that passes toward the south and into the buried valley aquifer. This is conservative from the perspective of preserving the water quality of the buried valley aquifer.

### 5.7.5 Simulation Results

The calibrated model, representing steady-state present conditions, indicates that approximately 2,330 ft<sup>3</sup>/day of flow enters the Site from upgradient in the "A" Horizon. Approximately 370 ft<sup>3</sup>/day is added on-site due to infiltration of precipitation. In the "B" Horizon, 5,350 ft<sup>3</sup>/day enters from the off-site upgradient and 600 ft<sup>3</sup>/day leaks in from the "A" Horizon on-site.

In the "A" Horizon, approximately 1,800 ft<sup>3</sup>/day leaves the Site by discharging into the Passaic River, 300 ft<sup>3</sup>/day flows laterally off-site toward the south, and 600 ft<sup>3</sup>/day flows downward into the "B" Horizon. In the "B" Horizon, approximately 920 ft<sup>3</sup>/day discharges upward into the Passaic River, 1,430 ft<sup>3</sup>/day under-flows the Passaic River and ultimately discharges into the buried valley aquifer, approximately 1,000 ft<sup>3</sup>/day flows off-site toward the north, and approximately 2,590 ft<sup>3</sup>/day leaves the Site by flowing southward, ultimately to discharge in the

river or the buried valley aquifer.

The results of the predictive simulation, which features an impermeable vertical wall (to be installed by the USACOE) penetrating from the water table to bedrock and extending from Bridge Street to Jackson Street along the Passaic River, demonstrate that the groundwater flow will be significantly affected by the wall. The simulation predicts that approximately 1,940 ft<sup>3</sup>/day of flow enters the Site from upgradient in the "A" Horizon. Approximately 370 ft<sup>3</sup>/day is added on-site due to infiltration of precipitation. In the "B" Horizon, 5,640 ft<sup>3</sup>/day enters from the off-site upgradient and 1,450 ft<sup>3</sup>/day leaks in from the "A" Horizon (compared to 600 ft<sup>3</sup>/day without the wall).

In the "A" Horizon, the barrier effectively prevents groundwater from leaving the Site by directly discharging into the Passaic River. Instead, 890 ft<sup>3</sup>/day flows laterally off-site toward the south, and 1,450 ft<sup>3</sup>/day flows downward into the "B" Horizon. In the "B" Horizon, approximately 1,030 ft<sup>3</sup>/day discharges upward into the Passaic River, 1,520 ft<sup>3</sup>/day under-flows the Passaic River and ultimately discharges into the buried valley aquifer, approximately 1,490 ft<sup>3</sup>/day flows off-site toward the north, and approximately 3,170 ft<sup>3</sup>/day leaves the Site by flowing southward, ultimately to discharge in the river or the buried valley aquifer (compared to 2,590 ft<sup>3</sup>/day without the wall).

# 6.0 MGP RESIDUAL INVESTIGATION

During the Site Screening, the remnants of several former MGP related structures were identified on-site. Some of these were physically discovered, while others were referenced on historic site plans. The locations, subsurface condition, and potential environmental impact were not known. The RIWP outlined an investigation using test trenches to identify former MGP related structures and associated contamination. The test trenches were excavated by Creamer Environmental and their locations are shown on Figure 8. The following sections describe the investigation findings.

### 6.1 Data Gap No. 11 - Valve House Investigation

The RIWP required the investigation into the source of the MGP residuals along the retaining wall on the Upper Tier of Parcel 1. During the RI, visible MGP residuals were observed along the retaining wall between borings B-18 and B-19. A concern was that the residual product was emanating from the former valve house (Figure 2) which was depicted on the historic site plans. To investigate this occurrence, a test trench (TT-10) (Figure 8) was installed on the upper tier side of the retaining wall to a depth corresponding with the observed tar-like product.

The trench was approximately 6 feet deep and encountered only fill material. At 1.5 to 2 feet below grade, a gravel layer was encountered that contained a tar-like material. The excavation was widened towards the retaining wall by 1.5 feet, and from 2 to 3 feet below grade where loose bricks were encountered that also contained the tar like material. At the bottom of the brick layer, a tar seep was observed. No evidence regarding the presence of the valve house or the source of the tar was found, therefore this data gap has not been closed. The tar encountered during excavation was replaced at its originally discovered depth.

### 6.2 Data Gap No. 12 - Delineation of MGP Residuals

The RIWP required the investigation into previously detected MGP residuals in the subsurface. MGP residuals were observed at various depths at five boring locations (B-2, B-6A, B-8, TWP-3 and P-4A) during the Site Screening. The extent of the residuals in these locations was unknown and required investigation. Please refer to Section 4.1 for a discussion of AOCs at the Site. Based on these AOC delineations, this data gap is closed.

### 6.3 Data Gaps No. 13 and 14 - Investigation of Former MGP Structures

#### Tar Tank - Northeast Corner of Lower Tier

An attempt was made to dig the trench (TT-1) through the center of the tar tank. This attempt failed as the tank was either completely encased in concrete, which could not be broken, or the concrete was the foundation for an aboveground tar tank. During the Site Screening, an unsuccessful attempt was made to advance boring B-7 through this tank. TT-1 and boring B-7A were performed adjacent to the concrete structure to a depth of approximately 5 feet. There were no observed MGP residuals adjacent to this structure, nor was there any evidence which would indicate what the structure was. For this reason, the structure is being referred to as simply a concrete vault on the figures.

### 20,000-Gallon Tar Tank - Adjacent to Passaic River

The trench (TT-2) was excavated to a depth of approximately 5 feet and encountered what appeared to be a foundation for an aboveground tank. There was no visual evidence of MGP residuals in this trench. For this reason, the structure is being referred to as simply a concrete slab on the figures.

During the Site Screening, B-8 was advanced through this slab. The boring found that the slab was approximately 3 feet thick. The log also describes free product contamination in the soils from approximately 7.5 feet to the bottom of the boring at 20 feet.

### 4,000-Gallon Tar Tank - Adjacent to Passaic River

The trench (TT-3) was excavated through the center of the tank which was either square or rectangular in shape (based on the walls having no curvature, the entire tank was not uncovered) with metal plating lining the inside of the concrete and brick walls of the tank. Water was trapped in the tank at a depth of approximately 2 feet. A tar-like product was encountered in the tank between 4 and 5 feet. TT-3 extended to a depth of 5 feet but did not encounter the bottom of the tank.

### 9,750-Gallon Tar Well - Lower Tier

A portion of the tar well was visible at the surface east of the 20,000-gallon tar tank investigated by TT-2. The dimensions of the tar well were approximately 25 feet by 13 feet. The top of the tar well had three 2 to 4 inch diameter holes which were probed to determine the contents of the well. The tar well was 5.5 feet deep and was almost completely full of water. There appeared to be a wooden piling of some sort visible in one of the larger holes. TT-4B was installed to a depth of approximately 5 feet perpendicular to the western edge of the well and there was no visual evidence of MGP residuals.

### Former Tar Separator Vault - Lower Tier

TT-5A & 5B uncovered a concrete vault and tar separator. TT-5A investigated the north edge of the concrete vault and TT-5B investigated the south edge of the vault and west side of the separator. TT-5A encountered tar inside the vault at approximately 5.5 feet, but there was no evidence of tar outside the vault. TT-5B discovered MGP residuals from approximately 4 to 5 feet (the bottom of the trench) outside of the vault. The remainder of the trench was excavated to 3 to 4 feet to avoid generating large quantities of impacted soil. The interior of this separator had one to two inches of MGP residuals on the bottom.

### 6,400-Gallon Tar Well and 4,000-Gallon Liquor Well

TT-6A was excavated from north to south in the assumed location of these two structures. The trench was excavated to a depth of approximately 5 feet and encountered neither the structures

nor MGP residuals. The trench did encounter the foundation of the brick building which caused water to enter the trench. TT-6B was installed near the water seep and extended to the east from TT-6A. This trench encountered no evidence of the tar or liquor wells nor MGP residuals.

#### Gas Holder #4 - Northwest Corner-Lower Tier

The trench (TT-7) was excavated through what was the assumed center of the holder and to a depth of approximately 7 feet. The trench only unearthed the northwest wall of the holder. The southeast wall was not encountered. There was no evidence of MGP residuals at this location. Borings B-6 and B-13 (Section 4.1) were installed inside the holder and revealed no MGP residuals on the floor of the holder at approximately 9 feet deep.

#### 115,000-Gallon Tar Tank and 80,000-Gallon Oil Tank

The trench (TT-8) was excavated through what was the assumed location of the tanks. TT-8 was installed to a depth of approximately 5 feet, but did not encounter the tanks. It is probable that these tanks were aboveground. A test hole was excavated during trenching to investigate the possible presence of a floor or foundation to the tanks. Between 7 and 9 feet, oily product was discovered. There was no evidence of a foundation.

Soil borings B-9 and B-14 were installed to investigate this area and encountered neither evidence of the tanks nor MGP residuals.

### Two 50,000-Gallon Oil Tanks

TT-9 was excavated on the ramp to the west of the oil and tar tank investigated by TT-8. The trench was excavated through what was the assumed location of the tanks. The trench was excavated to only approximately 5 feet bgs to protect the integrity of the retaining wall. The excavation did not encounter either the tanks or MGP residuals. Coal fragments were discovered from 1 to 2.5 feet below grade.

### Valve House - Upper Tier

The valve house was not located. The discussion for TT-10 and how it relates to the valve house has been provided as Section 6.1.

# Gas Holder #1 - Northern Portion - Upper Tier

TT-11A was excavated to bisect the gas holder to determine its approximate size. Two portions of the brick wall of the holder were uncovered during the trenching, and there was a slight MGP odor at approximately 8 feet deep at the approximate center of the holder. The trench was excavated to 10 feet below surface. TT-11B was installed to confirm a third point on the wall. The wall was encountered, but there was no evidence of MGP residuals in the trench. B-1 and B-29 were excavated inside the holder and found no evidence of MGP residuals. The bottom of the holder was encountered at 13 feet.

# Gas Holder #2 - Central Portion - Upper Tier

TT-12A was not excavated as proposed, since the subsurface condition and location of the holder was determined during UST removals (Section 7.1). TT-12B was excavated in the northwest portion of the holder and encountered the concrete wall. There was no evidence of MGP residuals in this location. The UST removal excavation discovered a one foot thick layer of MGP residuals in the bottom fill material. Some of this material was removed during the excavation of gasoline contaminated soil. B-2 encountered this material at approximately the same depth and encountered the bottom of the holder at approximately 12 feet deep.

# Gas Holder #3 - Southern Portion - Upper Tier

TT-13A was excavated from southwest to northeast across the holder. The trench was excavated to approximately 10 feet but did not encounter the holder bottom. An attempt was made on the northeast side to determine the depth, by extending the trench to approximately 14 feet deep. This attempt had to be stopped due to the large quantity of water which was encountered at approximately 11 feet deep in the holder. There were MGP odors present in the fill being removed from beneath the water. Borings B-3, B-3A, B-3B, B-24 and B-27 were all installed

inside the holder. The holder has a conical bottom with an approximate 2.5 foot rise toward the center. There was no inner ring wall observed in this holder.

# Tar Tank - Adjacent to Passaic River

TT-14 was added to the original scope of work upon the discovery of an historic site plan depicting a tar tank to the east of the tar separator vault. The trench encountered what appeared to be the corner of a structure (being referred to as the tar tank). There were MGP residuals in the excavation from 2.5 to 4 feet below grade. The bottom of the tank was encountered at 4 feet deep.

# 7.0 MISCELLANEOUS INVESTIGATIONS

### 7.1 Data Gap No. 15 - UST Removals

Eight USTs were previously identified at the Site which required location and removal. The first phase of the UST investigation involved locating the USTs via ground penetrating radar (GPR). The second phase involved removal and disposal of the USTs.

Advanced Geological Services performed the GPR survey to locate the USTs. Several traverses were made across the suspected locations of the USTs that identified the locations of USTs E-1, E-2 and E-3 within gas holder #2. The remaining five USTs were not identified by GPR. However, the fill pipes were discovered for USTs A-3, A-4 and E-4 east of gas holder #3. USTs A-1 and A-2 were located with a test pit during excavation activities within gas holder #2. All tank locations were confirmed upon excavation and are shown on Figure 2.

Between June 3 and 8, 1998, the eight USTs were removed by Creamer Environmental Inc. Construction Permits were obtained from the City of Newark (Appendix H), and the NJDEP was notified on May 14,1998. The copy of the notification to the DEP and facility questionnaire are on file with PSE&G.

Creamer Environmental excavated the overlying soil and exposed the top of each UST. For USTs E-3 and E-4 (contents listed on following table), a manhole was cut in the top of each tank using a spark free air chisel to allow access for tank cleaning. For the six gasoline USTs, Creamer inerted the interior of each tank by placing dry ice into the UST and allowing a sufficient amount of time to pass prior to cutting the tank open. After inerting the UST, a manhole was cut in each UST utilizing a spark free air chisel to allow access for tank cleaning.

After manholes were cut, Creamer Environmental entered the USTs to begin cleaning. All free standing product was removed by Clean Harbors via vacuum truck and transferred into an on-site

frac tank. Following the removal of the liquid product, the sludge in the bottom of each tank was removed by Lorco Petroleum Services via vacuum truck. After each tank was cleaned, they were removed from the excavation and placed on plastic for inspection (conditions of each tank are described in the following table). Following inspection, Creamer Environmental hauled the USTs off-site for disposal at a local scrap metal facility (receipts included in Appendix I).

UST A-1 and A-2 discharged gasoline to the subsurface inside holder #2. The fill material underneath and around these two USTs was saturated with gasoline. Because of the quantity of gasoline that was present in the holder, it was decided to excavate all material contaminated with free phase gasoline. Approximately 500 tons of soil were removed from the holder in an excavation depicted on Figure 15. Because the discharge occurred within a gas holder, excavation ceased upon encountering the wall and floor (10 to 12 feet below grade). Four post-excavation samples (EXC-1, 2, 3 and 4) were collected at the bottom side wall (approximately 10 feet bgs) of the excavation upon completion of the free product contaminated soil removal. Benzene and xylene were detected in the post-excavation soil samples at levels slightly above the most stringent NJDEP cleanup criteria (Table 9). Lead was also detected above the most stringent NJDEP cleanup criteria in sample EXC-3.

To investigate the possibility of gasoline migration through the holder wall, boring B-25 was installed northeast of the holder, in close proximity to the UST locations. The soils did not reveal any evidence of gasoline contamination and a sample collected at 11.5 to 12 feet bgs did not show contamination above the NJDEP SCC.

As discussed above, soil contamination was noted in the excavation for USTs A-1 and A-2. The contaminated soil was removed below these tanks and below E-1 and E-2 to the bottom of the former gas holder. The soil being removed was periodically evaluated for the presence of free product contamination using an organic vapor monitor (OVM) and performing soil/water agitation tests. Free product contaminated soil was immediately hauled off-site under Clean Harbors supervision. Soil was transported to and disposed of at an approved facility.

A summary of all waste removed by PSE&G is included in Appendix I.

In accordance with DEP protocols, PSE&G called the DEP Hotline and reported that a release had occurred from USTs which were being removed as part of a RI. PSE&G also indicated that the Case Manager was Mark Walters and that all other communications would be to him. The NJDEP issued case number 98-06-05-1215-15.

After the USTs were removed, post-excavation soil sampling was conducted to assess the impact the discharge from USTs A-1 and A-2 had on the subsurface soils. Post-excavation samples were collected from UST A-1, A-2, E-1 and E-2 along the excavation sidewalls due to the soil removal described above. All samples were collected in accordance with NJDEP-FSPM, and in accordance with N.J.A.C. 7:26-E. Soil samples were also collected from USTs E-4, A-3 and A-4 in accordance with N.J.A.C. 7:26-E. Results from sample E4-3, although above the most stringent NJDEP SCC can be attributed to the contamination associated with the drip leg located southeast of holder #3.

A description of each UST is provided in the table below. A UST sample location plan has been provided as Figure 15, the sample results have been summarized on Table 9 and a laboratory summary is provided as Appendix J.

| UST No.         | E-1      | E-2      | E-3    | E-4       | A-1        | A-2        | A-3      | A-4      |
|-----------------|----------|----------|--------|-----------|------------|------------|----------|----------|
| Length (ft.)    | 29       | 29       | 12     | 6         | 24         | 24         | 10.5     | 10.5     |
| Width (ft.)     | 6        | 5.8      | 5.5    | 4         | 5.3        | 5.3        | 4        | 4        |
| Capacity (gal.) | 6.000    | 6,000    | 2,000  | 550       | 4,000      | 4,000      | 1,000    | 1,000    |

| Construction    | steel    | steel    | steel  | steel     | steel      | steel      | steel    | steel    |
| Condition       | good     | good     | good   | good      | poor/holes | poor/holes | good     | good     |

# 7.2 Data Gap No. 16 - Soil Gas Investigation

One concern at the Site was the possible presence of volatile vapors in the subsurface. Previous investigations identified elevated PID/FID readings in overburden soils above the groundwater. To investigate the possibility of migrating vapors, a soil gas survey was conducted on June 2, 1998. Tracer Research Corporation of Monmouth Junction, New Jersey was retained to conduct the survey. Ten soil gas samples were collected along the northern, southern and western property lines (Figure 2). Samples were collected from the 0 to 2 feet bgs interval and field analyzed for BTEX. The findings of the investigation revealed no BTEX impact in the subsurface vapors.

# 8.0 SUMMARY OF FINDINGS

This section summarizes the findings and recommendations of the RI conducted at the Site. The information provided in this section is based upon the results of this RI. Section 8.1 summarizes the findings of the soil investigation. Section 8.2 summarizes the findings of the bedrock investigation. Section 8.3 summarizes the findings of the groundwater investigation. Section 8.4 summarizes the MGP structures investigation. Section 8.5 summarizes the findings of miscellaneous investigations conducted during the RI.

### 8.1 Soil Investigation

From the data collected, the following soil AOCs have been identified.

### 8.1.1 Shallow Soils

AOC-S1 encompasses the majority of Parcel 1. The concern in this AOC is the presence of elevated PAH and metal soil contamination in the surface soils (0 to 2 feet). No free product was observed within the soils, however, tar was observed immediately underneath the asphalt and elevated laboratory results were evident. AOC-S1 has not been fully delineated to the northwest and south, however, the presence of retaining walls along both of these property boundaries likely represents the extent of the contamination.

AOC-S2, a sub-area of AOC-S1, contains cyanide impacted soil at the surface in the southwest corner of the Lower Tier. This area requires additional investigation to determine the horizontal and vertical extent of impacted soil.

# 8.1.2 "A" Horizon Soils

AOC-A1 encompasses a majority of the Lower Tier of Parcel 1. The primary concern in this AOC is the presence of MGP residual free product. This product has been discovered above the semi-confining clay layer. Soil samples collected from this AOC exhibit elevated SVOC, VOC, and inorganic contamination. These soils may come into human contact during the construction of the river front park, and they represent a potential source of groundwater contamination. AOC-A1 has been fully delineated.

AOC-A2 encompasses the southern portion of the Upper Tier and extends westward across McCarter Highway into Parcel 2, off-site to the south, and east toward the Passaic River. The concerns in this area are the presence of MGP free product contamination in the saturated zone above the silt layer. Soil samples collected from this area exhibited elevated PAHs, VOCs, and inorganics. The contaminated soils in the upper tier and under Parcel 2 are at least 20 feet deep, while off-site to the south contaminated soil is encountered between 10 and 15 feet deep. AOC-A2 has not been fully delineated and requires further investigation.

## 8.1.3 "B" Horizon Soils

AOC-B1 encompasses a majority of the Lower Tier of Parcel 1. The primary concern in this AOC is the presence of MGP residual free product in the northeast corner. Soil samples collected from this AOC exhibit elevated concentrations of SVOCs and benzene. AOC-B1 has not been fully delineated and requires further investigation.

### 8.2 Bedrock Investigation

As discussed in Section 4.3, the former Ballantine Brewery used wells for process water. These wells were reportedly several hundred feet deep and open in the bedrock. Ballantine reported that water pumped from these wells contained tar. During the USACOE investigation, the

bedrock boring (S-3) installed at the southeast corner of the Site, revealed free product and PHC odors. Therefore, the bedrock was investigated.

The remedial investigation determined that the bedrock underlying the Site is composed primarily of siltstone. MGP residuals were observed in MW-3BR and MW-4BR at the southeast corner of the Site, corroborating the findings of the USACOE. The extent to which MGP residuals have migrated onto the former Ballantine property requires further investigation

### 8.3 Groundwater Investigation

Ten monitoring wells were installed (MW-1, 1A, 2, 2A, 3, 3A, 3BR, 4BR, 5BR, and 6) to further evaluate and delineate the extent of groundwater contamination under the Site. The results indicate that groundwater is contaminated with MGP residuals, predominantly, BTEX and naphthalene. The investigation has concluded that the primary source area for the dissolved phase volatile contamination is from AOCs A1 and A2.

Of the inorganics, iron and manganese exceedances can be assigned to the effects of anaerobic biodegradation, as previously discussed. Sodium is consistently high across the Site (even in the upgradient well MW-6). There are isolated exceedances of arsenic, lead and thallium that are insufficient to warrant action on their own. Aluminum above standards is more widespread and is also present in the upgradient well.

Groundwater contamination in the "A" and "B" horizons and the bedrock have not been fully delineated and requires further investigation.

# 8.4 MGP Structures

As the Site was an MGP plant in the late 1800s and early 1900s, a portion of the RI was conducted to determine the location and subsurface conditions of former MGP equipment and

facilities. A test trench program was implemented (in association with a number of soil borings) to delineate the remnants of these structures. Some of the oil and tar tanks which were indicated on historic plans were located. The locations of former MGP facilities have been depicted on figures within this report.

# 8.5 Miscellaneous Investigations

Eight USTs were removed from the Site during the RI. Two of the USTs had discharged gasoline into gas holder #2. The gas holder prevented migration of this gasoline into the groundwater. Contaminated fill from within the holder was excavated and hauled off-site. Some residual soil contamination was left but does not warrant further remedial actions because of the low concentrations detected and its isolation within the holder. This residual contamination will be incorporated into an overall Site deed notice.

A soil gas survey was conducted to determine if there were volatile vapors migrating off-site and impacting receptors. Soil gas samples collected from the south, west and north property lines found that there was no subsurface impact from volatile vapors. Therefore, there will be no impact on surface receptors.

The USACOE has conducted geotechnical studies along the Passaic River waterfront at or near the Site in connection with certain flood protection projects. These studies included the drilling of borings in the Passaic River at a number of locations including areas at or near the Site. Evidence of free product and/or black staining and strong PHC odors were observed in three of these locations. The Passaic River immediately north and south of the Site is currently being investigated by a third party at the direction of, and with supervision from, the USEPA. This investigation includes an extensive series of borings, a human and ecological risk assessment, and a feasibility study. It is believed that the USACOE data are being, or will be, considered in connection with this study. It is anticipated that the USEPA-directed investigation will be completed on or by 2001.

# 9.0 RECOMMENDATIONS

### 9.1 Introduction

The remedial investigation did not complete the delineation of soil and groundwater contamination related to the Site. PSE&G proposes to conduct additional investigations to close the remaining data gaps. The proposed work, as described below and depicted on Figure 16, will require access agreements with the surrounding property owners. The NJDEP will be notified in advance of conducting the work, and an RIR Addendum will be submitted providing the results of the investigation.

### 9.2 Soils

Soil contamination in the deeper "A" horizon was not delineated to the northwest of B-35 and southeast of B-47 (MAP Enterprises property). It is proposed to collect additional delineation samples based on the highest PID reading above the clay/silt layer. One soil sample will be collected northwest of B-35 at the intersection of McCarter Highway and Lombardy Place while installing proposed monitoring wells (see Section 9.3). Three soil samples will be collected from the proposed temporary well point (TWP) locations southeast of B-47. The soil samples will be analyzed for VO+10, SVO+20 and TAL inorganics.

#### 9.3 Bedrock

The bedrock investigation adjacent to the former Ballantine Brewery property detected MGP residuals. There are written descriptions as to the location of the former production well on this property. It is proposed to install a bedrock well (MW-11BR) at the former production well's location. The bedrock will be continuously cored to a stratigraphic depth corresponding to the fractured interval noted in the former artesian well and MW-3BR (approximately 107 feet bgs). Observations will be made on the bedrock structure and presence of MGP residuals. A well will

be installed and constructed of 20 feet of open screen starting approximately 10 feet into the bedrock surface. Groundwater from this well will be sampled as described in Section 9.4.

### 9.4 Groundwater

Groundwater contamination was not fully delineated in the "A" and "B" horizons. In order to delineate the plumes, a number of temporary well points and wells are proposed.

In the "A" horizon, nine groundwater point samples are proposed along the downgradient edge of the plume. Three points are located on Parcel 1 between previously installed points and wells to close data gaps. On the MAP Enterprises property, six points are located to define the plume toward the southeast. The points will be installed by augering to the water table and collecting a groundwater sample in accordance with Alternative Ground Water Sampling Techniques Guide (July 1994).

The groundwater samples will be analyzed for VO+10 and naphthalene.

Four wells (MW-7, MW-8, MW-9 and MW-10) will be installed in the "A" horizon following the groundwater point sampling. One well (MW-7) will be an upgradient well located at the intersection of McCarter Highway and Lombardy Place. One well (MW-8) will be located downgradient of B-26 on Parcel 1 to monitor groundwater quality in the middle of the Site along the river. One well (MW-9) will be located on the downgradient edge of the MAP Enterprise property based on TWP results. One well (MW-10) will be located adjacent to B-47 (MAP Enterprise property) to evaluate floating free product. The wells will be 2-inch PVC with the exception of MW-10, which will be 4-inch.

Four wells (MW-6A, MW-7A, MW-8A and MW-9A) will be installed in the "B" horizon to complete delineation. MW-6A and MW-7A will be paired with MW-6 and MW-7 to provide upgradient groundwater quality data. MW-8A will be paired with MW-8 to monitor

groundwater quality in the middle Parcel 1 along the river directly downgradient of P4 and P4A. MW-9A will be paired with MW-9 to assess the impact to groundwater quality in the "B" horizon.

At the completion of well installation, the proposed wells (including the bedrock well described in Section 9.3) will be sampled using the EPA's low-flow sampling technique. The samples will be analyzed for VO+10, SVO+20 and TAL inorganics. In addition, the sample from MW-6A will be analyzed for nitrate (NO<sub>3</sub>), sulfate (SO<sub>4</sub>), alkalinity, and total and dissolved iron to complete the natural attenuation assessment. The 18 existing wells and piezometers will be sampled at the same time using techniques from the Field Sampling Procedures Manual (May 1992). Groundwater samples collected from the existing wells will be analyzed for VO+10 and naphthalene only based on previous investigations. Quality control samples will include trip blanks, field blanks and duplicates.

### 9.5 RIR Addendum

The data collected will be used to: revise soil contamination maps to better delineate the "A" horizon; revise the groundwater contaminant isopleth maps; and to refine the aquifer model described in Section 5.7. These results will be presented to the NJDEP in an RIR Addendum.

#### Notes:

All results are shown in mg/kg. B ≈ Analyte detected in Field Blank. D ≈ Sample diluted prior to analysis. E ≈ Estimated value due to interference.

J = Detected below method detection limit. FT BGS = Feet Below Ground Surface

NA = Not Analyzed for this parameter

ND = Not Detected

NS = No Soil Cleanup Criteria. Shaded/bold = Parameter exceeds most stringent SCC.

Public Service Electric and Gas Company Former Front Street Gas Works

#### Notes:

All results are shown in mg/kg. B = Analyte detected in Field Blank. D = Sample diluted prior to analysis E = Estimated value due to interference J = Detected below method detection limit.

FT BGS = Feet Below Ground Surface NA = Not Analyzed for this parameter

ND = Not Detected

NS = No Soil Cleanup Criteria.

Shaded/bold = Parameter exceeds most stringent SCC.

Public Service Electric and Gas Company Former Front Street Gas Works

#### Notes:

All results are shown in mg/kg. B = Analyte detected in Field Blank. D = Sample dikted prior to analysis. E = Estimated value due to interference. J = Detected below method detection limit.

FT BGS = Feet Below Ground Surface NA = Not Analyzed for this parameter

ND = Not Detected

NS = No Soll Cleanup Criteria. Shaded/bold = Parameter exceeds most stringent SCC.

Public Service Electric and Gas Company Former Front Street Gas Works

#### Notes:

All results are shown in mg/kg. B = Analyte detected in Field Blank. D = Sample diluted prior to analysis. E = Estimated value due to interference. J = Detected below method detection limit.

FT BGS = Feet Below Ground Surface

NA = Not Analyzed for this parameter

ND = Not Detected

NS = No Soil Cleanup Criteria.

Shaded/bold = Parameter exceeds most stringent SCC.

Public Service Electric and Gas Company Former Front Street Gas Works

#### "A" Horizon Soll Sample Results

#### Notes:

All results are shown in mg/kg. B = Analyte detected in Field Blank. D = Sample diluted prior to analysis. E = Estimated value due to interference.

J = Detected below method detection limit.

FT BGS = Feet Below Ground Surface NA = Not Analyzed for this parameter

ND = Not Detected

NS = No Soil Cleanup Criteria.

Shaded/bold = Parameter exceeds most stringent SCC.

#### Notes:

All results are shown in mg/kg. B = Analyte detected in Field Blank. D = Sample diluted prior to analysis.

E = Estimated value due to interference. J = Detected below method detection limit.

FT BGS = Feet Below Ground Surface

NA = Not Analyzed for this parameter

ND = Not Detected

NS = No Soil Cleanup Criteria. Shaded/bold = Parameter exceeds most stringent SCC.

Public Service Electric and Gas Company Former Front Street Gas Works
