2016 New Jersey Integrated Water Quality Assessment Report

FINAL December 2019

Acknowledgements

New Jersey's integrated water quality assessment process requires the participation and expertise of many individuals. The Division of Water Monitoring and Standards gratefully acknowledges all who participated in the completion of this report. The Bureau of Environmental Analysis, Restoration and Standards (BEARS) Water Quality Assessment Team prepared this report under the direction of Director Bruce Friedman and Bureau Chief Kimberly Cenno.

Executive Summary

The 2016 Integrated Water Quality Assessment Report (Integrated Report) continues the comprehensive, regional approach to water quality assessment launched by the 2014 Integrated Report to support the identification of specific causes and sources of pollution, and to develop management measures tailored to the unique circumstances of one of New Jersey's five Water Regions each assessment cycle. This approach is important in identifying and managing all the sources contributing to water quality impairment (including point and nonpoint sources of pollution), land use planning, and other resource management tools. The Barnegat Bay Initiative served as a pilot for this approach, which was expanded to the entire Atlantic Coastal Water Region for the 2014 Integrated Report.

The 2016 Integrated Report focuses on the Raritan Water Region. The New Jersey portion of the entire Delaware River watershed will be the focus of the 2018/2020 Integrated Report. The Northeast Water Region will be the focus of the 2022 Integrated Report, after which the rotating regional assessment will return to the Atlantic Coastal Water Region in 2024. This approach will result in an extensive assessment of the entire State every 10 years as well as a comprehensive assessment of each water region that produces a greater number of thorough, validated, high confidence assessment decisions regarding ambient water quality conditions and the identification of data gaps. This report aims to guide future water quality sampling, sources of impairment on which to focus restoration activities, and new water quality issues for future investigation.

This report provides the information about New Jersey's water resources, current water quality conditions, and causes and sources of water quality impairment needed to inform and guide water quality monitoring, restoration and protection efforts conducted at the state, regional, watershed and local levels. The information provided in this report is also used Congress, U.S. the Environmental Protection Agency (USEPA), and the State of New Jersey to establish program priorities and funding for restoring, maintaining, enhancing and protecting waters of the State and the uses and benefits (public health, environmental, and economic) they provide.

The 2016 Integrated Report summarizes results of both short-term and long-term water quality analysis. The majority of the water quality data assessed for this report was generated during a five-year period, from January 2010 through July 2015. Such data provides a "snapshot" of regional water quality conditions over a relatively short period of time along with an overview of statewide water quality conditions as required to meet the federally-mandated, two-year

reporting cycle. Long-term monitoring data, including certain ambient chemical data, macroinvertebrate data, and fish population studies, provide a better indication of changes in water quality over time.

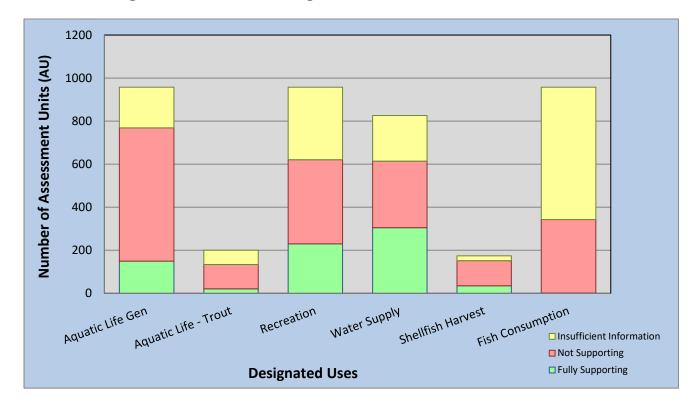

Figure ES-1: Statewide Designated Use Assessment Results, 2016

Water Supply: Thirty-eight percent of waters designated for the drinking water supply use fully support the use, 43 percent do not support the use, and 19 percent have insufficient information to assess the use. All New Jersey freshwater streams and lakes are designated for potential use as drinking water supply; however, most of the waters that do not support this use are not used for drinking water purposes. Arsenic is the predominant cause of water supply use impairment with 95% of impaired assessment units (AU's) exceeding the arsenic surface water quality standards

(SWQS) human health criterion for arsenic of 0.017 micrograms per liter (ug/L). The frequency of arsenic impairment has increased over time due to improved laboratory methods that detect arsenic at levels approaching the human health criteria and increased monitoring throughout the state.

Recreation: All waters of the State are designated for recreational use (e.g., swimming, boating). Most recreation occurs in ocean bathing beaches where all are fully swimmable. Overall, twenty-four percent of all New Jersey waters including lakes, ponds, rivers, and streams fully support the recreational use; 43 percent do not support the use; and 33 percent have insufficient information. The Department has addressed pathogens (fecal coliform, *E. coli, Enterococcus*) through development of total maximum daily loads (TMDLs), as a regulatory response for most of these impairments.

Aquatic Life: All waters of the State are designated for general aquatic life use and 81 percent have been assessed for this use. Seventeen percent of State waters fully support the general aquatic life use, 64 percent do not support the use, and 19 percent have insufficient information to assess the use. Fourteen percent of waters designated for the trout aquatic life use fully support this use, 59 percent do not support this use, and 27 percent have insufficient information. Impaired biological communities and nutrient-related parameters, particularly total

phosphorus (TP), are the primary cause of general aquatic life use impairment. Over 130 TP TMDLs have been established to date. Temperature is the primary cause of trout use impairment.

Shellfish Harvest for Consumption: Almost ninety percent of shellfish waters are classified as harvestable. Harvestable waters include: approved with no restrictions, seasonal harvest, and special restrictions. Only shellfish waters approved with no restrictions are considered to be fully supporting the designated use in the Integrated Report. Since an AU encompasses many shellfish classifications, the Integrated Report's conservative assessment method determines an AU as impaired if any of the classifications are not approved with no restrictions. The results indicate that 20 percent of New Jersey's AUs fully support this

use, 67 percent do not support this use, and 13 percent have insufficient information. Total coliform is the sole cause of shellfish use impairment and TMDLs have been developed for 79% of the impaired shellfish waters.

Fish Consumption: All New Jersey waters are designated for fish consumption. A very small percentage (<1 percent) of waters fully support the fish consumption use, 35 percent do not support the use, and 64 percent have insufficient information to assess the use. While there is a relatively small amount of data available, the majority of fish tissue data collected continues to show the impairment of the fish consumption use. The Department issues both statewide and waterbody-specific fish consumption advisories for such impaired waters.

Bioaccumulative toxic pollutants are the cause of fish consumption use impairment; however, many of these pollutants, such as PCB and DDT and its metabolites, are no longer manufactured and are considered "legacy" pollutants for which point source controls, such as wasteload allocations from TMDLs, are not effective restoration strategies.

The 303(d) List identifies pollutant causes of water quality impairment that require TMDL development. Causes already covered by an approved TMDL are identified on Sublist 4 of the Integrated List. The impairment list identifies 35 different causes of impairment for a total of 2,930 assessment unit (AU)/pollutant combinations (some AUs are impaired by multiple causes). Of all causes of water quality impairment, five of the top ten are associated with the aquatic life use, including biological impairments.

The most significant change to the listing methodology for the 2016 Integrated Report is the listing of biological assessment results. The new method lists all biological impairments based on macroinvertebrate and fish data whereas the previous listing methodology did not list biological impairments where there were other aquatic-life based chemical/physical impairments in an AU. The new listing methodology resulted in 228 biological listings on the 303(d) List that previously were not listed.

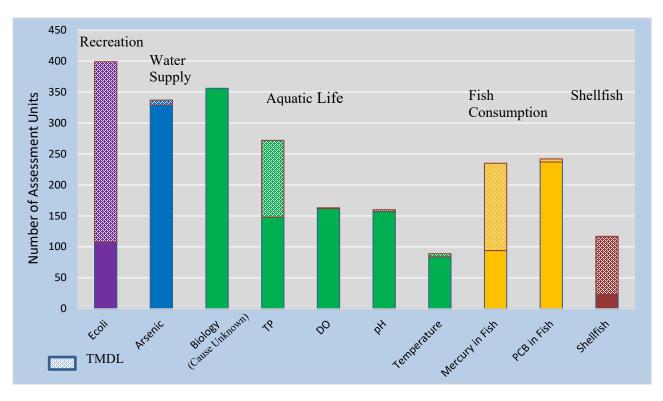

Figure ES-2: 2016 Top Ten Causes of Use Impairment

Over 150 AU/pollutant combinations were delisted from the 2016 303(d) List for various reasons (see Section 2.2). Forty-one percent of these delistings were due to water quality improvements while 47% of the delistings were due to an approved TMDL and placed on Sublist 4.

Trends: A recent USGS statewide water quality trend analyses¹ using data collected as far back as 1975 indicate that water quality has generally improved since the mid 1970's, particularly with respect to total phosphorus and total nitrogen (nutrients). This improvement is most likely due to the upgrade and regionalization of wastewater treatment plants that occurred throughout the State in the late 1980's through the early 1990's, as well as improved

treatment for nutrients in New Jersey Pollutant Discharge Elimination System (NJPDES) permits, implementation of nonpoint source pollution control programs, and stewardship activities at the local level aimed at reducing nonpoint source of pollution.

Declining water quality trends for nitrate, total dissolved solids (TDS) and chlorides were also observed. Ammonia reduction measures implemented at waste treatment plants oxidize ammonia to form nitrate, resulting in increased nitrate concentrations over time. Runoff from urban and agricultural areas, including runoff of salt used to control ice on roadways, are the likely cause of increased TDS and chloride concentrations over time.

Stable and improving nutrient trends are evident in the Raritan Water Region as well. In addition to chemical trends, biological trends and metal trends were observed in this region. Biological

trend analysis from 1999 to 2015 points to stable conditions with the majority of sites showing no changes over the 15vear period. However, there was an observable trend in the number of "Excellent" conditions and "Poor" conditions migrating toward the "Good" and "Fair" categories. The trends also show a correlation between biological impairment and anthropogenic factors such as land use, total urban land, increase in impervious surface, and decrease in forests and wetlands in a stream's drainage basin. The replacement of pervious land with impervious surfaces increases storm water and the associated impacts such as degraded riparian zones, unstable streambanks, higher turbidity, nutrients and other chemicals.

The most significant trend in the Raritan Water Region is the dramatic decrease of metal and ammonia levels in the region resulting in a 95% reduction of impairments on the 303(d) List since 1998. These results do not include arsenic which continues to be detected at levels that exceed the human health criteria. In 1998, there were 191 303(d) listings for metals including unionized ammonia. Years of monitoring has revealed only nine 303(d) listings for metals

remain in 2016. This improvement is the result of rules and regulations that have limited the discharge of toxins in the waterways and air, the remediation of contaminated sites, and the closing or shifting of many manufacturers out of the region.

The Department's strategic goal outlined in the "New Jersey Water Monitoring & Assessment Strategy (2005-2014)" to develop a comprehensive monitoring program for all waters of the state has resulted in drastic growth in the number of monitoring stations and samples collected over the last decade. In collaboration with other water monitoring stakeholders and agencies, the number of AUs with data has risen significantly. This trend has increased the number of samples used in the Integrated Report from approximately 300,000 data samples used in the 2006 assessment process to over 3.2 million discrete data samples and 1.8 million continuous data points for the 2016 Integrated Report. This data-rich environment has allowed the Department to increase the number of watersheds assessed and improve the validity of the assessments resulting in thorough, sound, high confidence assessment decisions.

For the 2016 Integrated Report, the Raritan Water Region underwent a comprehensive analysis to determine water quality in the region. The comprehensive assessment includes a detailed analysis of water quality and biological data, hydrography, land use, weather events, potential pollution sources, and historical data to confirm current water quality conditions. Restoration activities that are associated with improved water quality are identified as well as potential pollutant sources specifically in impaired waters that had minimal development or point sources. The comprehensive assessment also identifies data gaps to guide future water quality sampling, sources of impairment on which to focus restoration activities, and water quality issues for future investigation.

An analysis of land use demonstrates how developed land use and impervious surface impacts the aquatic ecosystem. Studies have shown that impervious surface is the most predictive and reliable land use indicator for biological integrity². These studies reveal that where impervious surface exceeds 10% of watershed land use biological degradation occurs. In watersheds where biota reflect healthy communities, the data show they are located in watersheds with healthy, forested riparian zones that include wetlands. Riparian areas are transitional areas between

terrestrial and aquatic ecosystems that are vital to watershed health. In watersheds with agricultural use or anthropogenic disturbance such as industrial, commercial, and residential development, the riparian zone provides a buffering between the stream and the area of disturbance. When observing impervious surface in riparian zones, the riparian buffer exhibits the highest sensitivity to disturbances in the watershed. In the Raritan Water Region, where impervious surface exceeds 10% in the riparian zone, the biological communities display extensive degradation with 90% of the biological communities impaired. Without a buffer to reduce the effects of stressors within the watershed, the biological communities are inundated and unable to recover. Development in the riparian zone degrades the benefits from a healthy ecosystem by intensifying storm water flow, destabilizes streambanks, increases levels of sedimentation and other nonpoint pollutants, rises water temperatures, damages stream habitat, reduces infiltration into the soil, as well as increases the frequency and intensity of flooding and low stream flows.

Over the last 10 years the Department has focused a strategy that allocated the resources needed to increase monitoring that has successfully reduced data gaps and achieved a stronger understanding of water quality conditions in the region. With this understanding of water quality issues in the Raritan Water Region, the Department has been able to initiate management actions to protect, maintain and restore water quality. Several significant efforts in the region include the approval of the Raritan TMDL, the "Non-Tidal Raritan River Watershed Protection Plan", and nonpoint restoration efforts. Since 1998, the Department has funded over \$11 million in nonpoint restoration projects including \$7.6 million since

2015. These actions along with future efforts are expected to reduce pollutant loading to help restore water quality.

In the effort to optimize resources for restoration efforts, the Department has initiated actions that identify and prioritize future nonpoint restoration efforts at a regional level. The goal of this effort is to maximize the utilization of restoration funding by identifying AUs that show the best potential for improving water quality, identifying areas within the AU that will have the most impact on water quality, and prioritizing these efforts. For the Raritan Water Region, 39 AUs were selected and vetted with stakeholders encompassing all four watershed management areas where AUs show the best potential in achieving water quality improvements to restore designated uses.

The Department administers numerous programs to restore, maintain, and enhance water quality. These programs include regulatory and non-regulatory water pollution control programs along with pollution prevention through education, outreach and stewardship programs for volunteer and community groups. The success of the Department's water quality management programs is supported by the results of the water quality trends analysis, which shows improving and stabilizing conditions over time (Chapter 2 and 3). These improvements are the result of significant financial investment, including millions of dollars in grants awarded for water quality

planning, restoration, land acquisition, and wastewater facility infrastructure improvements, operations, and maintenance (Chapter 5). Since its inception in 1987, the NJ Water Bank Program as financed approximately \$5.5 billion dollars to upgrade wastewater treatment facilities, reduce infiltration/inflow, control discharges from Combined Sewer Overflows (CSOs), construct sludge handling facilities, improve stormwater runoff, and close landfills. These investments have generated tangible results - increased beach days, trout waters, and shellfish harvests – that yield economic benefits for the entire State.

New Jersey is the fifth smallest and most densely populated state in the Nation. It is also one of the most geologically and hydrogeologically diverse states, with over 19,000 miles of rivers and streams; over 48,000 acres of lakes, ponds, and reservoirs; 950,000 acres of wetlands; 610 square miles of estuaries; 127 miles of coastline; and over 450 square miles of ocean under its jurisdiction. The combination of population density, diversity of natural resources, and a wide range of industries and land uses presents unique challenges to protecting New Jersey's water resources and these uses.

New Jersey's surface waters provide much of the water used for public drinking water, and serves as the primary resource for recreation, fish consumption and shellfish harvesting; yet most of the State's streams, lakes, ponds, bays, ground waters and ocean waters are impacted to some degree by both point and nonpoint sources of pollution. Protecting and restoring our water resources from such impacts has a direct and positive impact on the State's economy, particularly dollars generated by tourism, including recreational boating, swimming, and fishing, as well as from commercial fisheries, including shellfish, and the seafood industry. The Department estimates that the economic value of New Jersey's aquatic ecosystems at more than 19 billion dollars³.

The full 2016 Integrated Report is available on the Department's website at http://www.state.nj.us/dep/wms/bears/assessment.htm along with other related documents.

Table 5.1 is based on data from Table 4 of Part II of the report. Dollar amounts were converted from 2004 to 2009 dollars using the change in the Consumer Price Index for All Urban Consumers published by the U.S. Department of Labor's Bureau of Labor Statistics at http://www.bls.gov/cpi/.

³ NJDEP. Valuing New Jersey's Natural Capital: An Assessment of the Economic Value of the State's Natural Resources. April 2007. Available at http://www.nj.gov/dep/dsr/naturalcap.

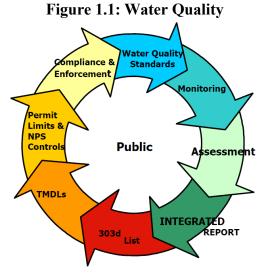

Chapter 1: Introduction

New Jersey is the fifth smallest and most densely populated state in the Nation and is one of the most geologically and hydrogeologically diverse. New Jersey has a variety of surface waterbody types that range from intermittent streams to large river systems (a significant number of which are tidally influenced); acres of lakes, ponds, and reservoirs; and miles of estuarine and coastal (ocean) waters. Wetlands are found near most surface waterbodies, both freshwater and saltwater. New Jersey's surface water systems are located in a wide variety of geologic settings, from the glaciated regions of northern New Jersey to the coastal plain of southern New Jersey and include ecologically unique and/or protected areas such as the Pinelands and the Highlands regions. This combination of population density, diversity of natural resources, and a wide range of industries and land uses presents unique challenges in protecting New Jersey's water resources.

New Jersey's surface waters provide much of the water used for drinking water supplies, recreation, fishing, boating, swimming, commercial fisheries including shellfish, and tourism, all of which State's ecology, quality economy, and of life for our The New Jersey Integrated Water Quality Assessment Report (Integrated Report) is a compilation of information about the quality of New Jersey's surface waters. The New Jersey Department of Environmental Protection (Department) prepares the Integrated Report as a biennial assessment of statewide water quality that identifies and prioritizes waters for protection, restoration, and additional monitoring or research. The Integrated Report thus serves as an effective tool for enhancing, maintaining, and restoring water quality in all surface waters of the State to support their use for aquatic life, recreation, water supply, fish consumption, and shellfish harvest for consumption.

1.1 - Overview of Integrated Water Quality Assessment

The primary purpose of the integrated water quality assessment program is to determine the health of New Jersey's water resources so the appropriate steps can be taken to restore, maintain and protect our water resources and their designated uses. Water quality standards, monitoring, and assessment provide the scientific foundation for the integrated assessment that supports protection of New Jersey's water resources and implementation of the federal Clean Water Act, the New Jersey Water Quality Planning Act, and the New Jersey Water Pollution Control Act (see Figure 1.1).

Counties

10

Municipalities

Water Quality Assessment

The Department initiates a new water quality assessment cycle every two years with the public solicitation of water quality data from other monitoring entities for a defined data collection and period. The Department compiles all existing and readily data for the specified available reporting period, evaluates the data to ensure that it meets established data quality requirements, and assesses the scientific data using methods developed specifically for the applicable type of parameter, designated waterbody use, and classification to determine compliance with New Jersey's surface water quality standards and support of applicable designated uses. methods are fully described in the Integrated Water Quality Assessment Methods (Methods Document) published the Department's website assessment (see http://www.state.nj.us/dep/wms/bears/ assessment.htm). Any changes to the Methods Document are published for public review and comment prior to the assessment of data to be used for the corresponding assessment cycle.

Raritan

Legend

NJ Pinelands Boundary

DRBC Assessment

Water quality data are compiled and

evaluated on both a station level, for attainment with applicable SWQS, and on an assessment unit level, for support of applicable designated uses, for all surface waters of the State. Assessment units (AUs) represent the scale at which waters of the State are grouped for assessment purposes. New Jersey waters are grouped into 958 AUs, which are delineated based on the U.S. Geological Survey (USGS) 14-digit Hydrologic Unit Code (HUC) boundaries except for waters of the Barnegat Bay Estuary and the Delaware River, and are grouped within five water regions (see Figure 1.2). The intra-state waters of the Delaware River are assessed by the Delaware River Basin Commission

(DRBC) based on their configuration of river "zones". The Department revised the AU boundaries for the Barnegat Bay in 2014, based on hydrologic and water quality data, to more accurately reflect conditions within the bay. Assessment unit boundaries are explained in more detail in the 2016 Methods

Document

(see http://www.state.nj.us/dep/wms/bears/docs/2016 final methods document.pdf). Assessment results are summarized in a draft Integrated Report, which is also published for public review and comment before it is formally submitted to USEPA for approval. Additional information about the assessment process, including prior assessment cycles, is available on the Department's website at http://www.state.nj.us/dep/wms/bears/assessment.htm.

Federal Reporting Requirements

The federal Clean Water Act (CWA) mandates that states submit biennial reports to the U.S.

Environmental Protection Agency (USEPA) describing the quality of their waters. CWA Section 305(b) requires submission of a biennial water quality inventory (305(b) Report) that assesses overall water quality and support of designate uses of all principal waters, as well as strategies to maintain and improve water quality. The 305(b) Reports are used by Congress and USEPA to establish program priorities and funding for federal and state water resource management programs. CWA Section 303(d) requires submission of a biennial list of water quality-limited waters (303(d) List), which identifies waters that are not supporting designated uses because they do not meet surface water quality standards despite the implementation of technology-based effluent limits. States must prioritize waters on the 303(d) List for development of Total Maximum Daily Load (TMDL)

Figure 1.3: Integrated Report 305(b) Report: 303 (d) List: Status of overall Identifies waters water quality that do not and support of meet surface designated uses water quality in the state. standards. Integrated Water Quality Assessment Report

analyses or alternative approaches and identify those high priority waters on the 303(d) List for which they anticipate establishing TMDLs in the next two years. These separate requirements were integrated in 2002 to produce one biennial Integrated Report (see Figure 1.3). This statewide assessment of water quality also provides a key component of New Jersey's Continuing Planning Process, in accordance with N.J.S.A. 58:11A-7(b) and 40 CFR 130.5(b).

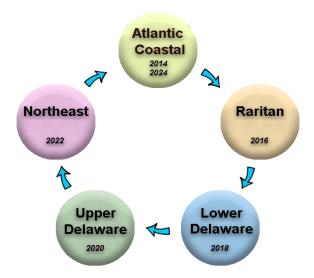

1.2 - Rotating Regional Approach to Water Quality Assessment

New Jersey employs an integrated approach to assessing water quality by compiling a vast amount of water monitoring data and related information collected by numerous sources throughout the state and evaluating it to determine the health of New Jersey's surface waters. This statewide

⁴ DRBC. 2016 Delaware River and Bay Water Quality Assessment. Delaware River Basin Commission. West Trenton, NJ. August 2014. Available on DRBC's Web site at http://www.state.nj.us/drbc/library/documents/WOAssessmentReport2016.pdf.

assessment of water quality is conducted every two years and includes a comprehensive assessment of one of the five water regions each assessment cycle. A different water region is selected each assessment cycle, on a rotating basis (see Figure 1.4). This integrated water quality assessment process is used to determine if water quality conditions have changed over time; if water quality standards are met and if designated uses, such as recreation and water supply, are fully supported; to identify causes and sources of water quality impairment; and to develop restoration strategies for impaired waters and protection strategies for healthy waters.

Figure 1.4: Rotating Regional Approach

Since 2014, New Jersey has employed this rotating regional approach to integrated water quality assessment. Under this approach, the Department conducts a streamlined assessment of statewide water quality along with a more comprehensive, detailed assessment of water quality in one of New Jersey's five water regions, Atlantic Coastal, Raritan, Lower Delaware, Upper Delaware and Northeast each assessment cycle. This rotating regional approach will produce a comprehensive assessment of the entire State every ten years and will support development of measures to restore, maintain, and enhance water quality tailored to the unique circumstances of each regions. This approach is consistent with U.S. Environmental Protection Agency (USEPA) guidance administering the federal Clean Water Act Section

303(d) Program entitled: "A Long-Term Vision for Assessment, Restoration, and Protection under the Clean Water Act Section 303(d) Program" issued in 2013. New Jersey's approach for implementing this guidance was submitted to USEPA and published as Appendix G of the 2014 Integrated Report, entitled: "New Jersey's Vision Approach for Assessment, Restoration, and Protection of Water Resources under the Clean Water Act Section 303(d) Program".

An updated Vision Approach is included in Appendix G of this report. This update explains how public participation and local commitment to a common goal of water quality restoration is needed to achieve fully supported uses in all waters of the State and what steps the Department is taking to engage stakeholders and the watershed community in the key aspects of the integrated water quality assessment process through outreach, monitoring, assessment and implementation (see Figure 1.5). This commitment to public involvement is reflected in the Department's redesigned quality water

Figure 1.5: Integrated Water Quality

http://www.state.nj.us/dep/wms/bears/assessment.htm#/, which shows the various stages of the integrated assessment process underway in each water region during each assessment cycle. An interactive mapping tool is being developed for this website to provide easier access to the data and assessment results on a statewide, regional, AU and waterbody level.

1.3 - 2016 Integrated Report

As explained under the Rotating Regional Approach to Water Quality Assessment, the 2016 Integrated Report provides both a statewide assessment of water quality and a comprehensive assessment of water quality in the Raritan Water Region (RWR). Assessment results describe the overall quality of New Jersey's surface waters based on existing, readily available data collected generally between January 1, 2010 and July 1, 2015. The Department compiled data available from various public data repositories and evaluated it to verify that the data met the Department's data quality requirements. Data was then assessed using scientific methods developed specifically for the applicable type of parameter, designated use, and waterbody to determine compliance with New Jersey's surface water quality standards (SWQS). These methods are described in detail in the final 2016 Methods Document.

While the majority of water quality data used for assessment purposes is generated by the Department, various monitoring organizations and other partners also collect relevant data. These include federal and county government agencies, regional commissions (e.g., Pinelands Commission) watershed associations and other voluntary citizen monitoring, and discharger associations. The Integrated Report is generated using data from all the Department's surface water quality monitoring networks along with relevant data from our monitoring partners that meets all data requirements and quality controls set forth in the corresponding Integrated Water Quality Assessment Methods (Methods Document). An explanation of any data sets not used for the 2016 Integrated Report is provided in Appendix E.

Water quality parameters are assessed as attaining or not attaining the applicable SWQS at each station for which there is sufficient data to compliance. Data from all stations located within each assessment unit (AU) are assessed collectively to determine if the applicable deisgnated uses are fully supported, not supported, or if there is insufficient information to assess the use. AUs assessed as "not supporting" a designated use include those that require a TMDL for pollutant cause(s) of use impairment as well as those covered by an approved TMDL that has not yet attained the applicable water quality standards necessary to fully support the use. These assessment results correspond to placement on the Integrated List of Waters (see Table 1.1), which identifies which waters are fully supporting all or some of the applicable designated uses (Sublists 1 and 2), which waters are not supporting one or more designated uses (Sublists 4 and 5), and which waters have insufficient data to assess use support (Sublist 3). Placement on these sublists enables the Department to develop, prioritize and implement appropriate response strategies including protection of high quality waters, additional monitoring to fill data gaps, and restoration activites to address impairment.

Table 1.1: Components of New Jersey's Integrated List of Water (Integrated List)

| Sublist 1/ Sublist 2 | An assessment unit is fully supporting designated uses and no uses are threatened. |
|----------------------|---|
| Sublist 3 | Insufficient data and information to determine if the designated use is fully supported or not supported. |
| Sublist 4 | One or more designated uses are not supported or are threatened but TMDL development is not required because of one of the following reasons: |
| Sublist 4A | A TMDL has been completed for the parameter causing designated use non-support. |
| Sublist 4B | Other enforceable pollutant control measures are reasonably expected to result in fully supporting the designated use in the near future. |
| Sublist 4C | Non-support of the designated use is caused by something other than a pollutant. |
| Sublist 5 | One or more designated uses are not supported or are threatened by a pollutant(s), that requires development of a TMDL. |
| Sublist 5A | Arsenic does not attain standards, but concentrations are below those demonstrated to be from naturally occurring conditions. |
| Sublist 5L | Designated use impairment is caused by a "legacy" pollutant that is no longer actively discharged by a point source. |
| Sublist 5R | Water quality impairment is not effectively addressed by a TMDL, such as nonpoint source pollution that will be controlled under an approved watershed restoration plan or 319(h) Watershed Based Plan. |

Sublist 5A (Arsenic Naturally Occurring) identifies AUs where arsenic does not attain standards, but concentrations are below those demonstrated to be from naturally occurring conditions; Sublist 5L (Legacy pollutants) identifies AUs where designated use impairment is caused by a "legacy" pollutant that is no longer actively discharged by a point source; and Sublist 5R (watershed restoration) identifies AUs for which water quality impairment is not effectively addressed by a TMDL, such as nonpoint source pollution that will be controlled under an approved watershed restoration plan or 319(h) Watershed Based Plan. Development of a watershed restoration plan can be an effective alternative to a formal TMDL to characterize pollutant sources, the reductions needed to attain standards, and the means to achieve the reductions. Pollutant causes of use impairment on Sublist 5 are placed on the 303(d) List, which also identified their priority ranking for TMDL development (H, M, L). TMDLs for AUs/pollutant combinations identified on Sublists 5A, 5L and 5R are assigned a low priority for TMDL development since alternative restoration measures are being pursued. The structure of the 2016 Integrated List and the rationale for each subpart is explained in more detail in the 2016 Methods Document (see 7.0 Integrated List Guidance).

Chapter 2: Statewide Water Quality

The 2016 Integrated Water Quality Assessment was completed using readily available chemical and biological monitoring data collected generally between January 2010 through July 2015, which was assessed in accordance with the 2016 Methods Document compiled and http://www.state.nj.us/dep/wms/bears/docs/2016 final methods document and response to com ments.pdf). The data were used to assess designated use support for all waters of the State and to identify pollutants causing designated use impairment. The use assessment results for each of New Jersey's 958 assessment units (AUs)⁵ are presented in the 2016 Integrated List of Waters (Integrated List)⁶, which is included in Appendix A of this report. Appendix A also includes a table of changes to designated use assessment results from the 2014 Integrated Report. The pollutant causes of use impairment in each AU are identified in Sublist 5 of the Integrated List, which also serves as the 2016 303(d) List of Water Quality Limited Waters (303(d) List) and is included in Appendix B. The 2016 303(d) List also includes the priority ranking for TMDL development, the listing station and cycle, the Sublist 5 subpart (where applicable) and the priority ranking for TMDL development. Appendix B identifies the sources of parameters causing use impairment and a table of TMDLs to be developed over the next two years. Causes removed from the 303(d) List and from Sublist 4 are included in Appendix C along with corresponding reasons and explanations. Decisions to not list causes on the 303(d) List is in Appendix D while data sources used to support the Integrated Report are identified in Appendix E.

The results presented in these appendices are summarized in Section 2.1 and 2.2. Section 2.1 focuses on use assessment results as well as the pollutants associated with impairment of each designated use. Section 2.2 summarizes key differences in the assessment results for the 2016 Integrated List compared to the prior cycle and identifies the new listings and new delistings to the 303(d) List and Sublist 4.

2.1 - Current Water Quality Conditions

The 2016 Integrated List (Appendix A) contains the use assessment results for New Jersey's 958 AUs. Each AU is assessed by the Department to determine if the applicable designated uses are fully supported, not supported, or not assessed due to insufficient information. Statewide use assessment results show that out of the 4,063 designated use results 48% of designated uses do not support use, 19% support use, and 33% have insufficient data.

⁵ New Jersey's waters are grouped for assessment purposes into hydrologically connected assessment units (AUs), most of which are based on United States Geological Survey (USGS) 14-digit Hydrologic Unit Code (HUC) boundaries. HUCs are geographic areas representing part or all of a surface drainage basin or distinct hydrologic feature as delineated by USGS in cooperation with the National Resources Conservation Service (NRCS). AUs containing the Barnegat Bay Estuary are delineated based on hydrologic and water quality data and modeling into 9 AUs that more accurately reflect conditions within the bay. Shared waters of the Delaware River mainstem, estuary, and bay are assessed based on the 8 Delaware River AUs delineated by the Delaware River Basin Commission (DRBC), which is responsible for assessing those intra-state waters.

⁶ Formerly referred to as the "Status of Designated Uses by Subwatershed Report", "Statewide Water Quality Inventory Report", or "305(b) Report" in previous Integrated Reports.

A summary of statewide use assessment results is provided in Table 2.1 and Figure 2.1. The water supply use has the highest percentage of use support (38%), followed by the recreation use (24%). The fish consumption use has the lowest percentage of use support (>1%). The general aquatic life use has the highest number of AUs with sufficient data for use assessment with 779 of 958 (81%) AUs with data and 17% of AUs fully support the use. Shellfish and aquatic life—trout designated uses apply to a relatively small number of AUs. Shellfish is fully supported in 20% of applicable AUs, while the aquatic life trout use is fully supported in 14% of applicable AUs.

Table 2.1: 2016 Statewide Designated Use Assessment Results (Number and Percent of AUs)

| Designated Use | Aquatic Life Aquatic | | tic Life | Recreation | | Water | | Shellfish | | Fish | | |
|-----------------------------|----------------------|-----|----------|------------|-----|--------|-----|-----------|---------|------|-------------|-----|
| | General | | Trout | | | Supply | | pply | Harvest | | Consumption | |
| Fully Supporting | 164 | 17% | 27 | 14% | 232 | 24% | 305 | 38% | 34 | 20% | 6 | 1% |
| Not Supporting | 615 | 64% | 116 | 59% | 410 | 43% | 353 | 43% | 118 | 67% | 339 | 35% |
| Insufficient Information | 179 | 19% | 56 | 27% | 316 | 33% | 159 | 19% | 22 | 13% | 613 | 64% |
| Total AUs | 9 | 58 | 199 | | 958 | | 817 | | 174 | | 958 | |

Figure 2.1: 2016 Statewide Designated Use Assessment Results

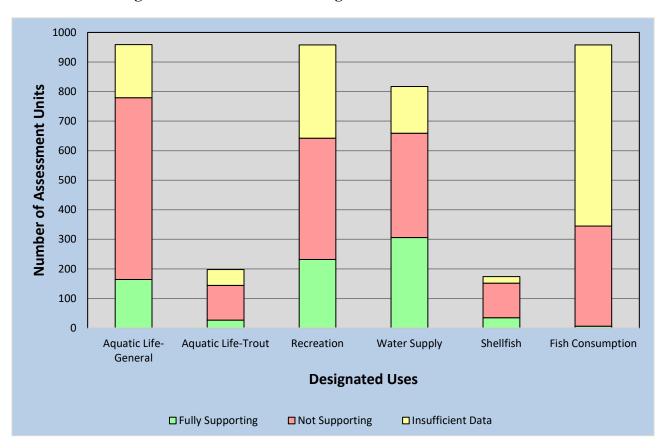

Figure 2.2 shows the number of AUs that fully support applicable designated uses in each Water Region. The Atlantic Coastal Water Region has the highest number of fully supported designated uses (284 AU/use combinations) of the New Jersey's Water Regions, followed by Upper Delaware (160), Lower Delaware (153), Raritan (100), and Northeast (72).

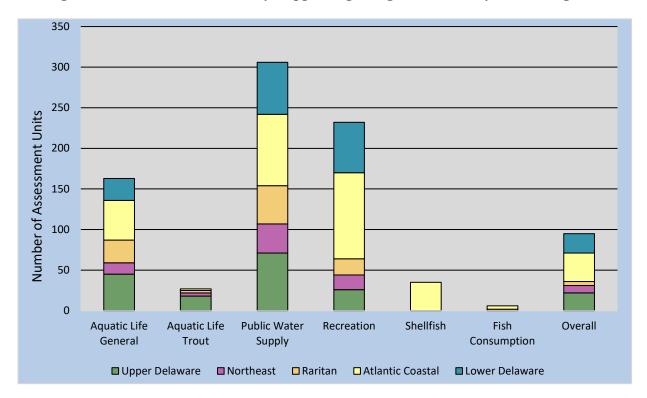

Figure 2.2: Number of AUs Fully Supporting Designated Uses, by Water Region, 2016

AUs assessed as not supporting a designated use include those that are impaired by pollutant causes that are not covered by an approved total maximum daily load (TMDL) and are placed on the 303(d) List, as well as those that are covered by an approved TMDL but have not yet attained the applicable water quality standards necessary to fully support the use, which are identified on Sublist 4 of the Integrated List. The impairment list identifies 35 different causes of impairment, for a total of 2,912 assessment unit (AU)/pollutant combinations. (Note: some AUs are impaired by multiple causes.) The most frequent causes of impairment or "designated use non-support" are shown in Figure 2.1 and are associated with the recreation, aquatic life, fish consumption, and water supply designated uses.

Figure 2.3 shows that *E. coli* is the most frequent cause of water quality impairment statewide and is associated with the recreational use. Most of these impairments (73%) are already covered under an approved TMDL. Biological impairments linked to benthic macroinvertebrate and fish communities are the second most frequent reason of water quality impairment and is associated with aquatic life use. Arsenic continues to show impairments statewide and is associated with the

water supply use. A number of these impairments are attributed to natural conditions but must still be categorized as impaired. PCB in fish tissue is the most frequent cause of fish consumption use non-support while high total coliform levels are impacting shellfish harvesting in our coastal waters.

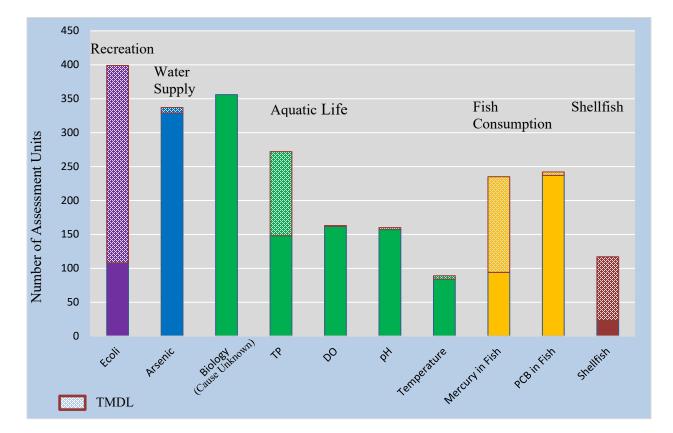

Figure 2.3: Top Ten Causes of Water Quality Impairment

These results reflect an increase in the number of impaired waters in New Jersey compared to previous reporting cycles; however, direct comparison between listing cycles as an indicator of water quality trends is problematic. In each listing cycle, there have been changes that affect the assessment universe and protocols for assessment decisions. For example, assessed areas were defined as stream segments, which kept changing as new waters were sampled; then HUC14 subwatershed became the basis for assessment, which provided a degree of uniformity from cycle to cycle, although there have been refinements to this universe. Additionally, improved detection limits for measuring pollutants, improved sampling techniques, improved equipment technology, and more rigorous assessment procedures have all contributed to changes in the number of possible assessment decisions and assessment outcomes over time. As we have witnessed in New Jersey, tremendous growth in new sampling has revealed more waterbodies that are impaired in previously unassessed waters. Longer term trends, discussed in Chapter 2 and Chapter 3, are considered to be better indicators in providing context for overall water quality status.

The most significant change to the listing methodology for the 2016 Integrated Report is the revised method of listing biological assessment results based on benthic macroinvertebrate and fish community data on the 303(d) List. The newest method lists all biological impairments on the 303(d) List based on macroinvertebrate and fish data which are represented by "Biological - Cause Unknown." Whereas the previous listing methodology only listed biological impairments when there were no other aquatic-life based chemical/physical impairments in an AU, the new method lists all biological impairments on the 303(d) List regardless of other aquatic-life based chemical/physical impairments. The previous method was based on the presumption that the chemical/physical impairment was exclusive based the macroinvertebrate/fish impairment, however, it is known that biological community impairments are impacted by other stressors such as loss of habitat, hydrologic alterations, increased storm flow, and riparian zone modifications. This action clarifies the listing methodology in that it includes all known impairments that are causing aquatic life designated use non-support on the Integrated List/303(d) List. Additionally, this methodology allows the Department to more accurately address biological impairments in waterbodies by identifying the issues, developing the proper management strategy, and implementing the most effective restoration actions to address the impairments. The new listing methodology resulted in 228 biological listings on the 303(d) List that previously were not listed.

In addition, two new indices were developed to address biological assessment gaps; Barnegat Bay Macroinvertebrate Index (BBMI) and Headwaters Index of Biotic Integrity (HIBI). The BBMI is based on the Multivariable AZTI Marine Biotic Index (M-AMBI)⁷ to assess the health of the benthic community in the Barnegat Bay based on research conducted by Rutgers University (all four reports located at https://www.nj.gov/dep/dsr/barnegat/final-reports/#Benethic_Invertebrates). The widely accepted and locally validated index was originally developed in Europe, but has since been improved and modified to include waters in the Virginia Provence, which extends from Cape Cod to the Chesapeake Bay. The HIBI was developed to assess streams less than four square miles in watershed area within the northern ecoregions. This new index monitors the assemblage of fish as well as crayfish, salamanders and frogs to assess aquatic life use in small headwater streams.

The Department's strategic goal outlined in the "New Jersey Water Monitoring & Assessment Strategy (2005-2014)" to develop a comprehensive monitoring program for all waters of the state has resulted in drastic increase in the number of monitoring stations and samples collected over the last decade. In collaboration with other water monitoring stakeholders and agencies, the number of AUs with data has risen significantly and has resulted in a comprehensive understanding of water quality conditions. Since 2006 which is the first Integrated Report that AUs were based on HUC14 sub-watersheds, the number of unassessed designated uses caused by insufficient data declined by 22% to only 23% AUs with insufficient data, the number of AUs with at least one designated use assessed rose to 97% statewide, and the number of AUs where all of the designated uses are assessed rose over 30% to 55% statewide.

⁷ Borja A., Mader J., Muxika, I. 2012. Instructions for the use of the AMBI index software (Version 5.0). Revista de Investigación Marina, AZTI-Tecnalia 19:71-82.

⁸ Does not include fish consumption designated use where 64% have insufficient data. The increase of new sampling has not included fish tissue monitoring that has remained relatively stable and does not include

For the 2006 Integrated Report, approximately 300,000 data samples were used in the assessment process. Since that time, the number of samples used in the assessment process has exploded exponentially wherein the 2016 Integrated Report downloaded over 3.2 million discrete data points and 1.8 million continuous data points. This data-rich environment has allowed the Department to increase the number of watersheds assessed and improve the validity of the assessments resulting in thorough, sound, high confidence assessment. In order to manage, review, process, and quality control such a large set of data and data results, it was required to automate the assessment processes by incorporating advanced technology and programming languages. It was determined the best solution to handle these datasets was using the R statistical language to manage the data, automate the assessment process, and generate tables, maps, and graphs to present the results. The R language is an advanced, open source statistical language that is free to all users, cross-platform compatible, flexible, easy to learn, comprehensive, produces outstanding graphics and has a vast community of users and programmers, who share their programs. Although since 2006, the Integrated Report assessment process used Microsoft Access that included automated assessment processes, the new R program is expected to achieve a 70% reduction in time to perform the data management, assessment, and graphics processes. The 2016 Integrated Report was the first year using the R program and required extensive programming and quality control, therefore time efficiencies will be realized in future Integrated Reports.

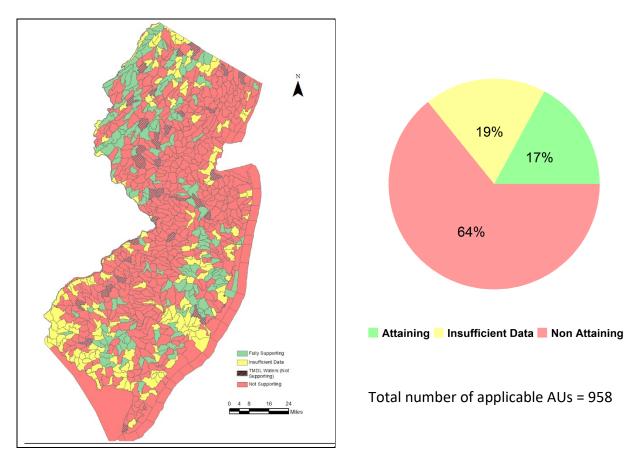

Statewide assessment results for each of New Jersey's designated uses are discussed in the rest of this section, along with the assessment results for key parameters associated with each of the designated uses: General Aquatic Life, Trout Aquatic Life, Recreation, Public Water Supply, Shellfish Harvest for Consumption, and Fish Consumption.

large areas of the state. The Department recognizes this data gap and has implemented actions to reduce the number of unassessed sub-watersheds.

General Aquatic Life Use: All waters of the State (958 AUs) are designated for the general aquatic life use. Seventeen percent (17%) of AUs fully support the use, 64% do not support the use, and 19% are not assessed due to insufficient information (see Figures 2.4A and 2.4B).

Figure 2.4A: Assessment Results for General Aquatic Life Use, Spatial Extent

Figure 2.4B: Assessment Results for General Aquatic Life Use, Percent (%)

The general aquatic life use is assessed based on a suite of key parameters. Five of these key parameters: TP, dissolved oxygen (DO), pH, temperature, and biological-cause unknown, are among the top ten causes of water quality impairment statewide, as shown in Figure 2.1. Nutrient enrichment from point sources (e.g., sewage treatment plants), land use practices (e.g., application of fertilizer), and land disturbance (e.g., loss of riparian buffers and increase in impervious surface), are common sources of these impairments. Biological impairments have been identified as the most frequent reason for aquatic life use impairments. Although causes are unknown for the biological degradations, the Department is developing strategies that will address these impairments and implement the most effective restoration actions. TP has been identified as the most frequent chemical parameter causing impairments and has been a focus for TMDL development, with 131 TMDLs completed by the Department to date. DO and pH-caused impairment are often associated with nutrient over-enrichment that will respond to restoration efforts aimed at controlling nutrients. It is noteworthy that, in the course of developing TP TMDLs, the Department found that a number

of AUs considered to be impaired by temperature might actually reflect natural conditions. A more in-depth analysis of these impaired AUs is underway to determine if temperature reflects natural conditions or actual use impairment. The charts below reflect the relative assessment status of biological and chemical parameters associated with the general aquatic life use.

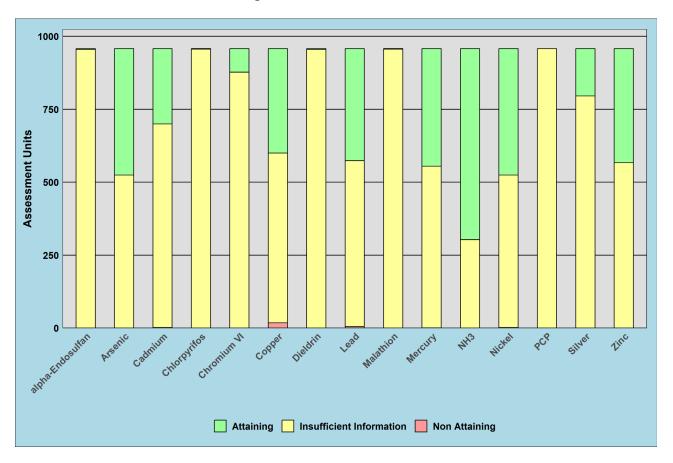

Total Processing Proce

Figure 2.5: Assessment Results for Key Associated with General Aquatic Life Use, of 958 AUs⁹

Metals and toxins were not a significant cause of aquatic life use impairment statewide. At only 2%, copper had the highest number of exceedances of aquatic life criteria for metals, with all other metals and toxins falling below 1% or fully supporting.

⁹ While the aquatic life use applies to all 958 AUs, some AUs contain waters without corresponding criteria for each pollutant associated with that use. For example, there are no numeric criteria for TP in saline waters. Therefore, TP can only be assessed in AUs that contain freshwaters. The percentages shown are based on the total number of applicable AUs for each pollutant associated with the general aquatic life use.

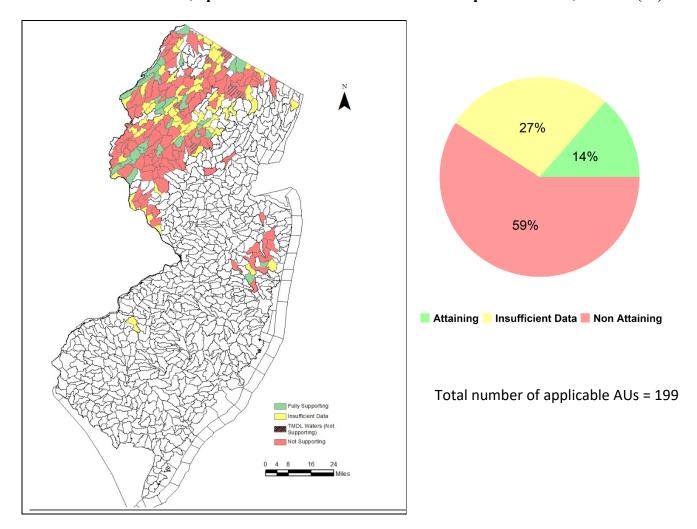

Figure 2.6: Assessment Results for Metal and Toxin Parameters Associated with General Aquatic Life Use of 958 AUs

Trout Aquatic Life Use: The trout aquatic life use only applies to 199 of New Jersey's 958 AUs since this use is reserved for waters classified as trout maintenance or trout production. Fourteen percent of these AUs fully support the use, 59% do not support the use, and 27% are not assessed due to insufficient information (see Figures 2.7A and B). The critical parameters for assessing this use are temperature, dissolved oxygen and biological data.

Figure 2.7A: Assessment Results for Trout Aquatic Life Use, Spatial Extent

Figure 2.7B: Assessment Results for Trout Aquatic Life Use, Percent (%)

The predominant cause of trout aquatic life use impairment is temperature, which accounts for 67% of the AUs assessed as not supporting the trout aquatic life use. Criteria for temperature are more stringent in trout production and trout maintenance waters than in other waters of the state because of the sensitivity of the target species. Other causes for trout aquatic life use include biological impairments, TP, and pH shown in Figure 2.8. All data for metals and toxins are fully supporting the trout aquatic life use (see Fig 2.8 and 2.8B).

Figure 2.8: Assessment Results for Key Parameters Associated with Trout Aquatic Life Use, Percent (%) of 200 AUs

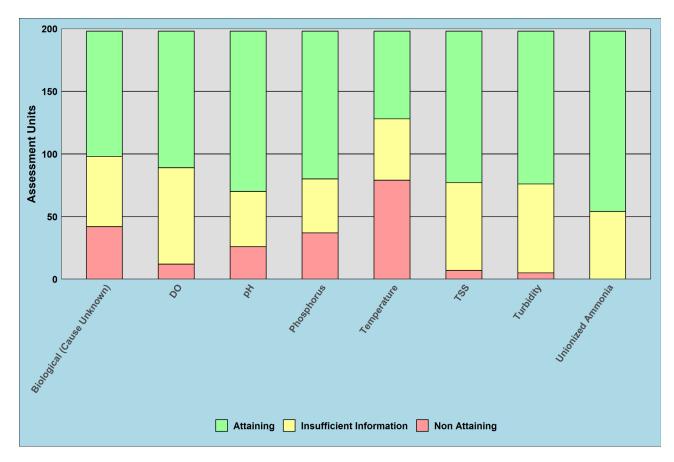

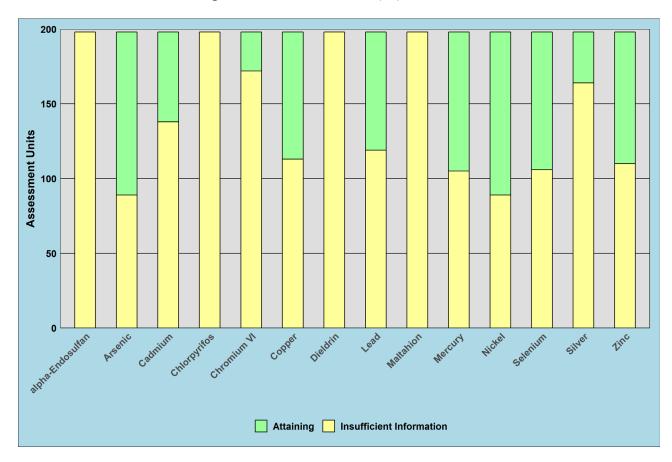

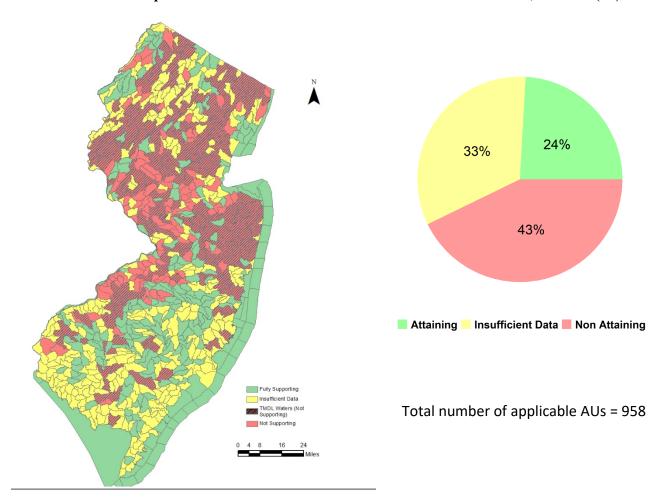

Figure 2.8B: Assessment Results for Metal and Toxin Parameters Associated with Trout Aquatic Life Use, Percent (%) of 200 AUs

Recreation Use: All waters of the State (958 AUs) are designated for recreational uses. Twentyfour percent fully support the use, 43% do not support the use, and 33% are not assessed due to insufficient information (see Figures 2.9A and B). Assessment of ocean beaches, where most bathing occurs, shows that these waters are fully swimmable from Sandy Hook to Cape May Point.

Figure 2.9A: Assessment Results for Recreation Use, **Spatial Extent**

Figure 2.9B: Assessment Results for **Recreation Use, Percent (%)**

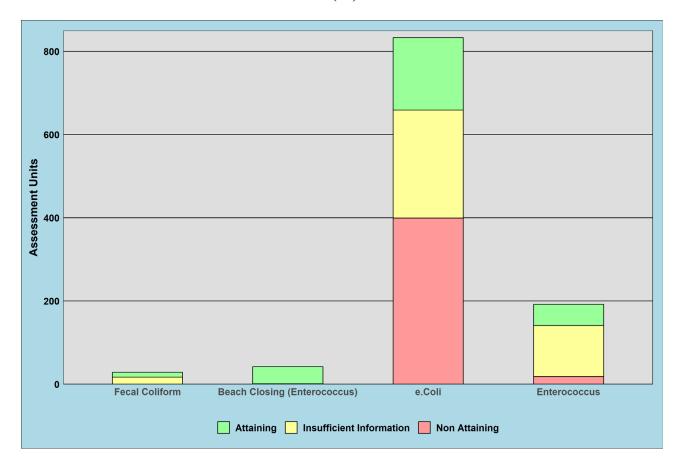

The recreation use is assessed based on the presence of pathogenic bacteria indicators (E. coli and Enterococcus). 10 New Jersey's coastal waters and estuaries demonstrated more consistent support for recreation than freshwaters (streams, rivers, and lakes). Freshwaters represent over 80% of recreational use impairment. Figure 2.10 shows a much higher percentage of impaired AUs caused by E. coli (97%), the freshwater pathogen indicator, than AUs caused by Enterococcus (3%), the saline water pathogen indicator. All ocean beaches are fully supporting recreational use with only one back bay beach in Toms River Estuary impaired based on beach closure data. TMDLs have

¹⁰ Prior assessments were based on fecal coliform; however, this parameter was replaced with E. coli and Enterococcus based on USEPA guidance. Prior listings for fecal coliform are carried over to the 303(d) List if newer pathogen data is not available.

been completed for most (73%) of the waters that do not support recreational uses because of pathogens.

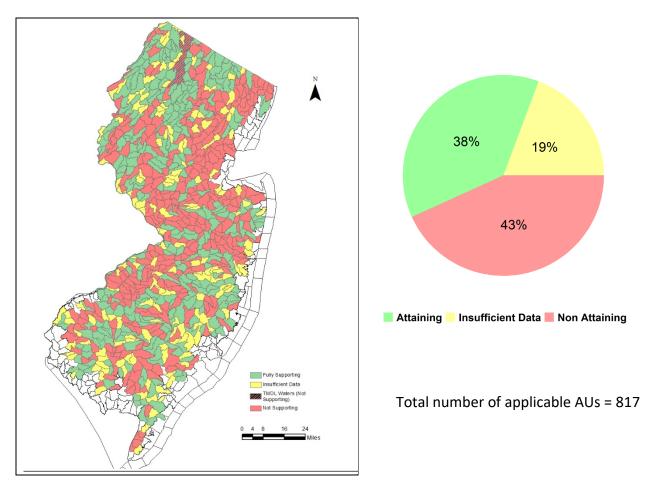

Figure 2.10: Assessment Results for Key Parameters Associated with Recreation Use, Percent (%) of AUs

Public Water Supply: All New Jersey freshwater streams and lakes, located in 817 AUs, are designated as potential potable water supplies. The water supply use has the highest percentage of use support (38%) of all designated uses statewide; however, 43% also do not support the use and 19% are not assessed due to insufficient information (see Figures 2.11A and B). Most of the waters that do not support the public water supply use do not contain potable water intakes and are not currently used for drinking water purposes.

Figure 2.11A: Assessment Results for Public Water Supply Use, Spatial Extent

Figure 2.11B: Assessment Results for Public Water Supply Use, Percent (%)

The critical parameter for assessing this use is nitrate; however, the water supply use is assessed as impaired ("not supporting") if any parameter exceeds the applicable human health criterion. Arsenic is the predominant cause of water supply use impairment with 95% of the impaired AUs impacted by arsenic (see Figure 2.12). The frequency of arsenic impairment has increased over time due to improved laboratory detection of arsenic at levels approaching the SWQS human health criterion for arsenic of 0.017 micrograms per liter (ug/L). This human health criterion is much more stringent (by more than an order of magnitude) than the New Jersey maximum contaminant level (MCL) of 5 ug/L established in the Safe Drinking Water Act rules at N.J.A.C. 7:10-5.2 (see

http://www.nj.gov/dep/rules/rules/njac7_10.pdf). Although the same health risk factors are used to develop the MCL and SWQS human health criteria, the Safe Drinking Water Act takes into consideration additional factors such as the feasibility of treatment, cost, and analytical capabilities to set the MCLs for all treatment facilities. Surface water quality criteria are based solely on data and scientific research on pollutants and their environmental and human health effects, they do not consider economic or social impacts. The result is 41% of the AUs are not supporting based on the SWQS human health criteria, but only a few waterbodies (Maurice River, North Branch Metedeconk River, and Sharps Run) have arsenic concentrations above the drinking water MCL. Additionally, a significant number of waterbodies located in the Coastal Plain (southeastern New Jersey) exceed the human health criteria for arsenic but at concentrations that are equal to or less than the naturally-occurring concentrations of arsenic for that geologic formation. Even though these are natural conditions, EPA policies on carcinogens requires these waters to be listed as impaired. Other causes of water supply use impairment include total dissolved solids (TDS), lead, mercury in the water column, and nitrate, but at very low percentages statewide (3% or less).

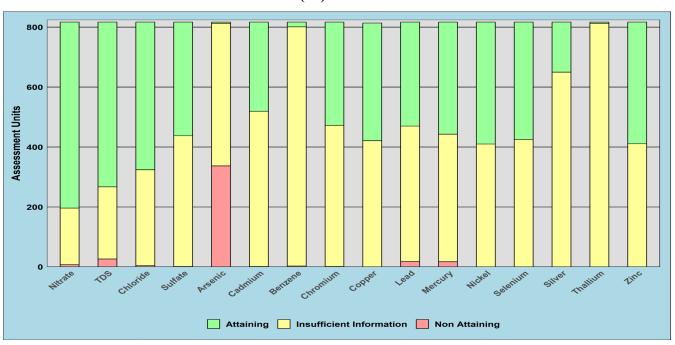

Figure 2.12: Assessment Results for Key Parameters Associated with Water Supply Use, Percent (%) of 826 AUs

Barringer, Julia L. and Reilly, Pamela A. et al, 2013, Arsenic in New Jersey Coastal Plain Stream, Sediments, and Shallow Groundwater: effects from Different Geologic Sources and Anthropogenic Inputs on Biogeochemical and Physical Mobilization Processes USGS Scientific Investigations Report 2013-5107. https://pubs.er.usgs.gov/publication/sir20135107

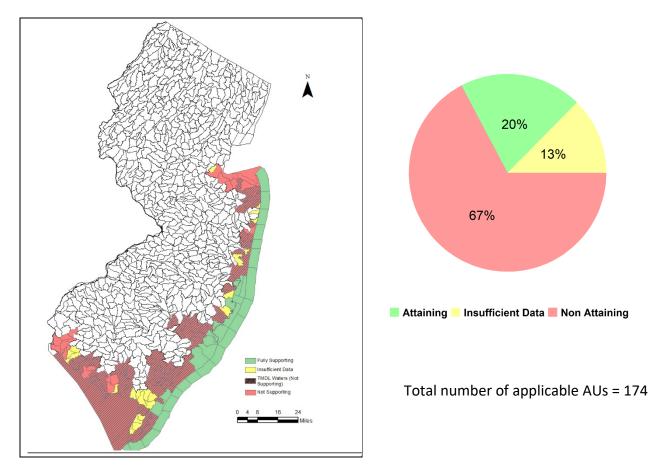

Barringer, J.L., Mumford, A., Young, L.Y., Reilly, P.A., Bonin, J.L., Rosman, R., May 2010, *Pathways for Arsenic from Sediments to Groundwater to Streams: Biogeochemical Processes in the Inner Coastal Plain, New Jersey*, USA Water Research vol. 44, p. 5532-5544. http://www.ncbi.nlm.nih.gov/pubmed/20580401

¹¹ Studies conducted by USGS have found that the natural levels of arsenic range from 0.24-0.61 ug/l in the Outer Coastal Plain, and 0.36-0.70 ug/l in the Inner Coastal Plain. Arsenic exceedances that are within these naturally-occurring concentrations will be identified on the 2016 303(d) List as Sublist 5A (arsenic naturally occurring).

Shellfish Harvest for Consumption: Waters only capable of being harvested for shellfish are assessed; therefore only 174 of New Jersey's 958 AUs (18%) are assessed for this use. Federal shellfish classification requirements stipulate three categories of harvestable shellfish: "approved" (with no restrictions), "seasonal harvest" (harvestable only parts of the year), and "special restrictions" (additional depuration treatment required). For this report, shellfish waters classified as "approved" are only reflected as fully supporting the designated use. The results show twenty percent of applicable AUs fully supporting the use, 67% not supporting the use ¹², and 13% having insufficient information to assess the use (see Figures 2.13A and B).

Figure 2.13A: Assessment Results for Shellfish Use, Spatial Extent

Figure 2.13B: Assessment Results for Shellfish Use, Percent (%)

Pathogen TMDLs have been developed for most of the AUs assessed as not supporting the shellfish harvest for consumption use (79%). These TMDL waterbodies are located exclusively in the bays

¹² AUs assessed as not supporting the shellfish harvest for consumption use include shellfish waters classified as harvestable with seasonal restrictions and harvestable with special restrictions (i.e., depuration treatment is required), as well as waters where shellfish harvest is prohibited.

and tidal rivers. Ocean waters are 100% fully supporting shellfish harvesting. Areas in the ocean classified as "prohibited" in harvesting charts are administrative closing with no water quality data exceeding criteria. As explained in the Methods Document, administrative closures of shellfish are established in areas around potential pollution sources, such as sewage treatment plant outfalls, marinas, and outfalls as a preventive measure to avoid the harvest of shellfish that could become contaminated by sewage, boat wastes or stormwater runoff. Where shellfish harvest is prohibited due to an administrative closure, such prohibited areas are not included in the overall shellfish use assessment. Hence any ocean AUs containing administrative prohibited areas are not included in the assessment and the other waters in the AU are assessed which all show "approved" conditions.

As depicted in Figure 2.13A and 2.13B, the percent of applicable AUs assessed as fully supporting differs from the percent of shellfish waters classified as harvestable (Figure 2.14) which includes "approved", "seasonal harvest", and "special restricted" waters. USEPA guidance for the Integrated Report requires that only AUs where shellfish waters are classified as "approved" with no restrictions can be assessed as fully supporting the shellfish harvest for consumption designated use. Since an AU encompasses many shellfish classification areas, the Integrated Report's conservative assessment method determines an AU as impaired if any of the classifications within the AU are "prohibited", "seasonal harvest" or "special restricted." This results in many of the AUs with a large area of approved waters being classified as impaired because of smaller areas with harvest restrictions. More information about shellfish classifications including detailed maps is available on the Department's website at http://www.state.nj.us/dep/wms/bmw/info01.htm.

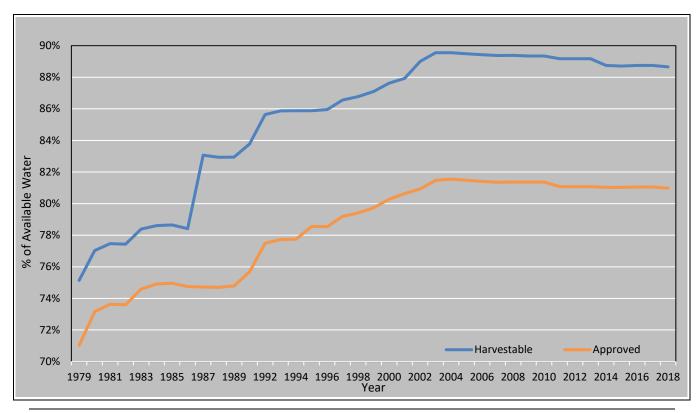

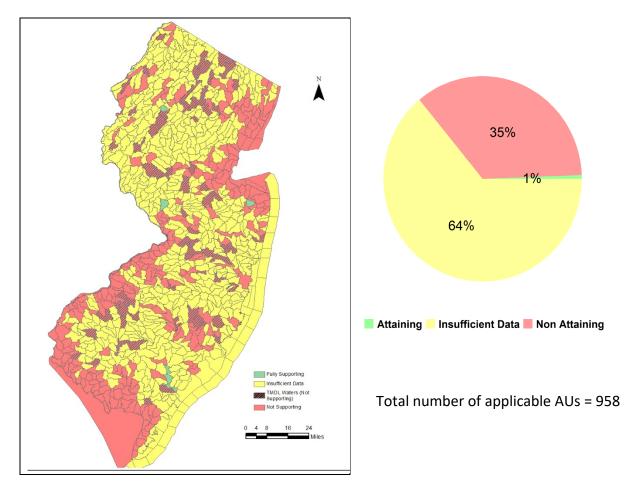

Figure 2.14: New Jersey Harvestable Shellfish Waters

Fish Consumption: All waters of the State (958 AUs) are designated for the fish consumption use. Six AU (1%) fully support the use, 35% do not support the use, and 64% are not assessed due to insufficient information (see Figures 2.15A and B). The critical parameters for assessing this use are common bioaccumulative toxic pollutants that are used for fish consumption advisories (see Figure 2.15C). The Department uses fish tissue data to identify exceedances of human health criteria and waterbody-specific fish consumption advisories for these pollutants to determine fish consumption uses. ¹³

Figure 2.15A: Assessment Results for Fish Consumption Use, Spatial Extent

Figure 2.15B: Assessment Results for Fish Consumption Use, Percentage (%)

¹³ Consumption advisories may restrict the amount and/or the type of fish consumed and there may be different advisories for high-risk populations and the general public. The Department issues both statewide and waterbody-specific advisories for the general population and for high-risk groups including infants, children, pregnant or nursing mothers, and women of childbearing age. (See Section 6.3 of the 2014 Methods Document and the Department's Web site at http://www.nj.gov/dep/dsr/njmainfish.htm.)

While there is a relatively small amount of data available, the majority of fish tissue data collected continues to show the impairment of the fish consumption use. The most frequent causes of fish consumption use impairment are also among the top ten causes of water quality impairment statewide: mercury in fish tissue, PCB in fish tissue, and DDT (and its metabolites). PCB and DDT (and its metabolites) are no longer actively manufactured; therefore, the Department considers these to be legacy pollutants for which a TMDL is not an effective means to restore water quality. ¹⁴

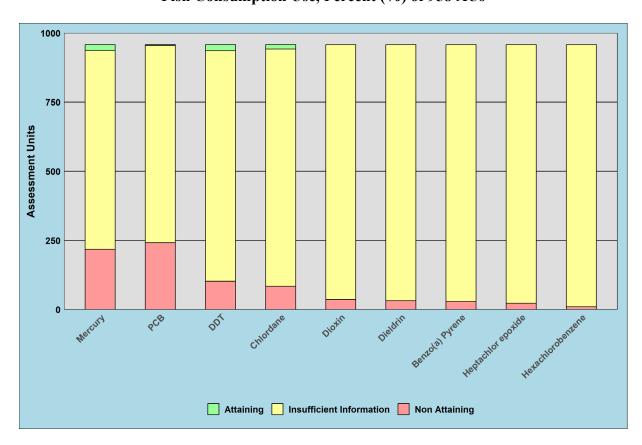

Figure 2.15C: Assessment Results for Key Parameters (in Fish Tissue) Associated with Fish Consumption Use, Percent (%) of 958 AUs

2.2 - Changes from Prior Assessment

Section 2.1 summarizes the assessment results of designated uses and their associated pollutants, as well as the most frequent causes of use impairment. This section focuses on significant changes to Sublists 4 and 5 of the Integrated List, which identify causes of use impairment. Sublist 4 identifies causes of use impairment that are already covered under or do not require an approved TMDL. Sublist 5 identifies causes of use impairment that require development of a TMDL (i.e., the 303(d)

¹⁴ A new subcategory of the 303(d) List has been created for legacy pollutants (see Chapter 7 of the 2014 Methods Document, Appendix E).

List). Parameters added to the 2016 303(d) List are considered "new listings". Parameters that were on the 2014 303(d) List but were removed are considered "new delistings". USEPA only allows delistings under certain circumstances. New listings, delistings, and the corresponding reasons, are summarized in Table 2.2A and explained in more detail in Appendix C.

Table 2.2A: 2016 Sublist 5/303(d) New Listings and Delistings

| | New | Delisting ² | Reas | Net | | |
|------------------------------|----------------------|------------------------|-------------------------|-------------------|--------------------|--------|

- 1. New listing to the 303(d) List
- 2. Total delistings from 303(d) List
- 3. Delisted based on water quality data showing attainment of applicable water quality standards
- 4. Delisted from 303(d) List based on an approved TMDL and moved to Sublist 4
- 5. Delisted based on administrative correction or assessment methods change

Parameters identified as new causes of water quality impairment that are already covered by a TMDL (and were not identified on a previous 303(d) List) are placed on Sublist 4.¹⁵ Causes were removed from Sublist 4 if data showed that water quality standards were attained (moved to Sublist 1 or 2) or there was an assessment error and insufficient information was available to assess water quality (moved to Sublist 3). New causes added to or removed from Sublist 4 are summarized in Table 2.2B.

Table 2.2B: 2016 Sublist 4 New Causes Added or Removed

| Pollutant | New Causes | Causes | Reason for R | Net Change | |
|------------------------------|--------------------|----------------------|--|---------------|----|

| Total Coliform | 1 | | | | 1 |
| Total Suspended Solids (TSS) | | | | | |
| Total | 8 | 10 | 7 | 3 | -2 |

^{1.} Cause added directly to Sublist 4 in 2016 because it is covered by an approved TMDL; was not a prior 303(d) Listing

Parameters Delisted or Removed as Causes of Water Quality Impairment

The top five delistings from the 2016 303(d) List are TP, TSS, DO, E. coli, and pH. The delistings

^{2.} Total causes removed from Sublist 4

^{3.} Removed from Sublist 4 based on water quality data showing attainment of applicable water quality standards

^{4.} Removed from Sublist 4 based on administrative correction or assessment methods change

¹⁵ USEPA does not consider removal from Sublist 4 to be a "delisting", even if it results from attainment of applicable water quality standards, because the cause was removed ("delisted") from a prior 303(d) List when the TMDL was approved.

for DO and pH are predominately based on new data showing attainment of applicable water quality standards, 88% and 79% respectively. *E. coli* and TP delisting are predominately based on approved TMDLs, 94% and 82% respectively, while TSS delisting are based on both new data (45%) and TMDLs (40%). Overall, 39% of delistings are based on attainment of applicable water quality standards and restoration of the designated use to fully supporting, 46% are based on applicable TMDLs, while the remainder are delisted based on administrative correction or assessment methods changes. Causes removed from Sublist 4 include mercury in fish tissue, *E. coli*, and TP. All of the mercury in fish tissue removals were based on data showing attainment of applicable water quality standards, along with 50% for *E. coli* and TP. Overall, 80% of the Sublist 4 removals are based on attainment of applicable water quality standards and restoration of the designated use to fully supporting.

Parameters First Listed or Added as Causes of Water Quality Impairment

The top five causes representing new listings on the 2016 303(d) List are biological impairments, arsenic, *E. coli*, TP and DO. Biological assessments attributed to 55% of the new listings on the 303(d) List, however, these listings were due to administrative changes to the listing methods and do not necessary reflect a significant decline of water quality. A net zero change in *Enterococcus* listings reflects the continued excellent recreational water quality in New Jersey's ocean waters, as well as stable conditions in the bays and estuaries. The new causes added to Sublist 4 are enterococcus, mercury in water column, TP, and total coliform.

Figure 2.16 illustrates changes to Sublists 4 and 5 contributed by each Water Region, based on the number of new listings/causes added and delistings/causes removed. As expected, the comprehensive assessment of the Raritan Water Region generated the highest number of new listings and delistings/removals (see Section 2.3).

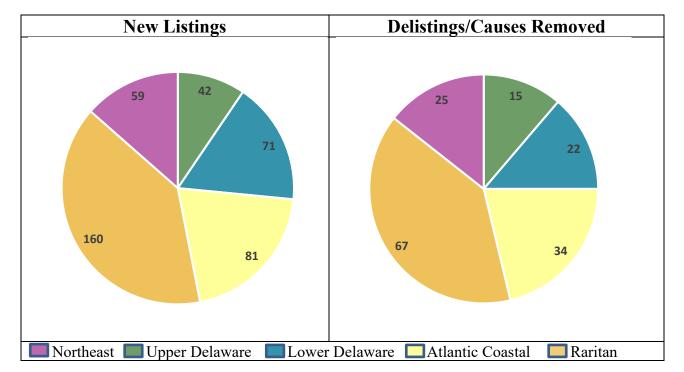

Figure 2.16: Changes to Sublists 4 and 5 by Water Region

2.3 - Statewide Long-Term Trends

Much of the water quality data supporting the integrated assessment are collected over a five-year period, which provides a "snapshot" of conditions during that timeframe. Evaluating data over longer periods allows us to identify water quality trends and acute conditions that would otherwise not be apparent.

Several water quality trends, typically over a ten-year time period, are discussed in prior Integrated Reports. With regard to improving the statistical assessment of water quality trends in New Jersey, the USGS recently completed a new robust statistical trend analysis demonstrating water quality trends in the state over a much longer time period than previous trend reports¹⁶. Nutrient data from 28 physical/chemical monitoring sites distributed throughout the state were analyzed by a Weighted Regressions on Time, Discharge, and Season model (WRDTS) using data over a 30-year time period (1980 to 2011), and by the Seasonal Rank-Sum test comparing data from the 1970s to the 2000s. The WRDTS summarized data into annual values and then examined trends through selected periods; the Seasonal Rank summarized data by decade and then examined trends between any two decades. Nutrients analyzed in both methods included total phosphorus (TP), total nitrogen (TN), and nitrate. Also analyzed were a series of indicators of major ions in the water column: specific conductance (SpCond), chlorides (Cl), and total dissolved solids (TDS), however, analysis for these three constituents were limited to four locations along the Delaware River Drainage.

¹⁶ Hickman, R.E. and R.M. Hirsch. 2017. Trends in the Quality of Water in New Jersey Streams, Water Years 1971-2011. SIR 2016-5176. USGS. Reston, VA.

Using WRDTS, TP and TN showed improving conditions with compelling downward or stable trends throughout the state. TP exhibited downward or no trends at 27 of 28 sites, while TN had 26 of 28 sites with downward or no trends. Trends for nitrate demonstrated stable or downward trends for only 19 of 28 sites, while nine sites had increasing trends. Results employing the Rank Sum method were similar; TP and TN had robust results confirming decreasing and stable trends, while nitrate showed more mixed results with an equal number of increasing and decreasing sites. Trends for the major ion indicators showed chlorides and TDS to be increasing in almost all situations, while specific conductance results indicated either upward trends or no trends at all four sites.

The improvements with TN and TP were expected considering the upgrades to wastewater treatment and the implementation of statewide nonpoint source management efforts over the time period assessed. As stated in the 2014 Integrated report, the late 1980s and 1990s saw a significant upgrade in sanitary treatment quality. In 1980, most sanitary treatment plants in New Jersey were limited to primary treatment, but in 1988 most plants were required to upgrade to secondary treatment. Secondary treatment required additional treatment to remove organic compounds by biological processes. Concurrently, in the mid-1980s many smaller primary plants were taken offline and the sewer systems were regionalized into larger more efficient secondary plants resulting in the removal of the smaller inefficient primary plants from water basins. Additionally, nonpoint source controls began to expand in the late 1990's with the implementation of the Municipal Separate Storm Sewer (MS4) and Nonpoint Source Permitting Programs. These programs continue to be implemented and prioritized to the present.

Although TN demonstrated improving water quality, the oxidized form nitrate showed mixed results. As discussed in earlier Integrated Reports, decreases of ammonia are often accompanied by increases in nitrate as treatment plants oxidize the ammonia to eliminate it. Ammonia is more deleterious to the environment than the more oxidized species of nitrogen through its uptake of oxygen and its toxicity to aquatic life. The results in the trend analysis showed an overall reduction of nitrogen, however, the upgrade to treatment plants and their resulting efforts to reduce ammonia could have led to increases in the oxidized form (nitrate).

Increases in TDS and chlorides have been observed in almost all trend assessments performed to date. TDS, specific conductance, and chloride increases have been associated with runoff from urban, suburban and agricultural areas, especially runoff of salt to control ice on roadways. Winter storm-related data support correlations between road salting and increased TDS levels in the water column.

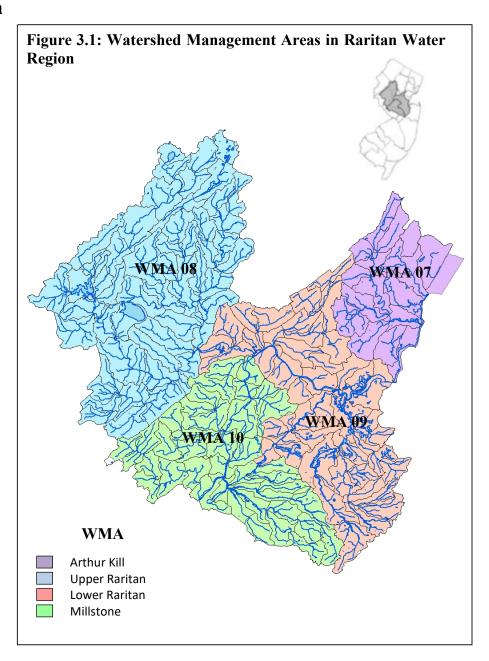

2.4 - Summary of Statistical Survey Methods and Results (reported online)

Probabilistic monitoring used to generate statistical estimates of water quality conditions statewide to support USEPA's national aquatic resource surveys are found on the USEPA website https://www.epa.gov/national-aquatic-resource-surveys.

Chapter 3: Raritan Water Region Water Quality

3.1 - General Information

Raritan Water Region covers a total watershed area of 1,260 square miles divided into 156 AUs and encompasses 122 consisting municipalities approximately 3 million people. It includes portions of Essex, Hunterdon, Mercer, Middlesex, Monmouth, Morris, Somerset, and Union counties. The region is divided into four watershed management areas (WMAs): the Arthur Kill, Upper Raritan, Lower Raritan, and Millstone (Figure 3.1). The Arthur Kill (WMA 07) includes the Arthur Kill, Elizabeth River, Rahway River, and Woodbridge River. The Upper Raritan (WMA 08), includes the North and South Branches of the Raritan River and major tributaries such as Neshanic Creek, Rockaway Creek, and Lamington River. The Lower Raritan (WMA 09) includes the mainstem of the Raritan River where the North Branch and South Branch join to the mouth of the river where it drains into the Raritan Bay. Major tributaries include Green Brook, Lawrence Brook, South River, Manalapan Brook, Deep Run and Matchaponix Brook.

The Millstone (WMA 10) includes the Millstone River and Stony Brook watersheds as well as the Delaware and Raritan Canal.

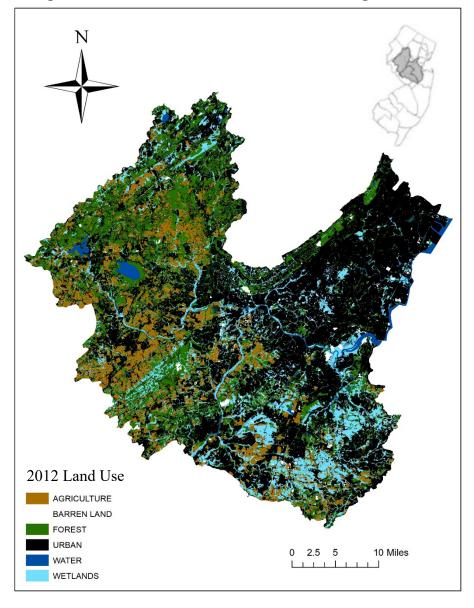

Land use in the region has changed drastically over the last 50 years and the most current land use analysis in the region in 2012 reveals that 48% is urbanized, 13% is agricultural use, 23% is forested, and 16% is wetlands and waterbodies (see Figure 3.2). Activities and runoff from the various land uses have significant impact on water quality and are discussed in this section.

3.2 - Outreach

Sustainable Raritan River Initiative

The Department's outreach to stakeholders in the Raritan Water Region was initiated through the efforts of the Rutgers University Sustainable Raritan River Initiative (SRRI). The SRRI was instrumental in coordinating. facilitating, and supporting the stakeholder engagement efforts with the Department for the development of the Integrated Report and the vision for water quality restoration and protection in the Raritan Water Region.

Figure 3.2: 2012 Land Use in Raritan Water Region

The SRRI was launched in 2009 bringing together community leaders, businesses, academia, environmental stewards and government agencies to protect and restore the Raritan River Watershed. The initiative emphasizes science-based policies for sustaining the ecological, economic, and community assets associated with the Raritan. As a key collaborator, Rutgers University provides technical assistance to assist public officials, businesses and non-profit groups in developing policies, programs, and projects to support the protection and restoration of the Raritan. The SRRI addresses major issues of concern including water quality; stormwater management and infrastructure; stewardship; habitat restoration and protection; remediation, rehabilitation and reuse of abandoned and underutilized properties; public access and recreational use of the river; climate resiliency; and sustainable development. Additionally, the initiative

supports outreach and collaborative efforts such as workshops, annual conferences, and community outreach through its website, social medial and newsletters.

The Department and SRRI put forth considerable effort into the stakeholder engagement and outreach efforts through workshops coordinated by SRRI. These stakeholder meetings in June 2016, November 2016 and February 2017 focused on presenting draft water quality results from the Integrated Report, protection and restoration priorities, and funding for nonpoint source restoration. These engagements were critical in soliciting input from the stakeholders in the region on water quality issues, recommendations on strategies and goals for restoration and protection, and identifying data gaps for future monitoring. The SRRI's efforts to engage, follow-up, and document the outreach efforts was instrumental in the success of the program. A summary of these efforts are available on the SRRI website at http://raritan.rutgers.edu/the-initiative/raritan-integrated-report/.

Other important accomplishments by SRRI include the publication of their "State of the Raritan Report: Volume 1 and Volume 2" at http://raritan.rutgers.edu/2016-state-of-the-raritan-report/. These reports provide an overview of conditions in the Raritan River watershed by using key indicators of water quality and watershed health. These documents are intended to provide metrics to inform planning, identify data gaps and research needs, as well as provide the baseline of metrics that can be used to measure progress in the protection and restoration of watershed.

3.3 - Current Water Quality Conditions

For the 2016 Integrated Report, the Raritan Water Region underwent a comprehensive analysis to determine water quality in the region. The comprehensive regional assessment process allows the Department to improve confidence in its assessment decisions by conducting a detailed analysis of environmental conditions in the region using water quality and biological data, hydrography, land use, weather events, and potential pollution sources. These were used to determine water quality at monitoring stations and to confirm station associations with specific AUs to determine the spatial extent each station represents. The comprehensive regional assessment also allows for consideration of results from nearby sampling stations and historical data to confirm current water quality conditions. Restoration activities that are associated with improved water quality are identified as well as potential pollutant sources specifically in impaired waters that had minimal development or point sources. The comprehensive assessment of the Region resulted in an increase in the number of thorough, validated, high confidence assessment decisions regarding ambient water quality conditions. The comprehensive assessment also identified data gaps to guide future water quality sampling, sources of impairment on which to focus restoration activities, and new water quality issues for future investigation.

A summary of the Region use assessment results is provided in Figure 3.3. The water supply use has the highest percentage of use support (31%), followed by the general aquatic life use (18%), recreational use support (12%) and trout aquatic life use (8%). The fish consumption use has the lowest percentage of use support (1%) with shellfish designated use only applying to two AUs in the region. While both Raritan and statewide results showed similar conditions for general aquatic life use, public water supply use, and fish consumption; conditions in the Region were worse for recreational use and trout aquatic life use (see Table 3.1).

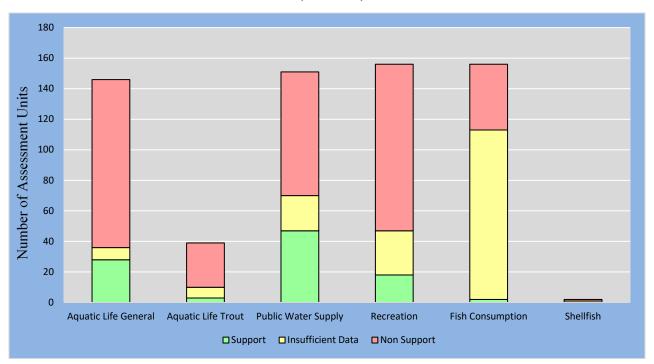

Figure 3.3: 2016 Designated Use Assessment Results for the Raritan Water Region (156 AUs)

| Total AUs Applicable | 817 | | 1 | 151 174 | | 74 | | 2 | 9 | 58 | 1! | 56 |

Figure 3.4 shows that *E. coli* is the most frequent cause of water quality impairment in the Region as it is statewide. Most (66%) of these impairments are already covered under an approved TMDL. The most frequent cause of aquatic life use impairments are biological impairments and TP. Arsenic continues to show impairments in the region and is associated with the water supply use. Mercury in fish tissue is the most frequent cause of fish consumption use not being attained with 66% covered by a TMDL.

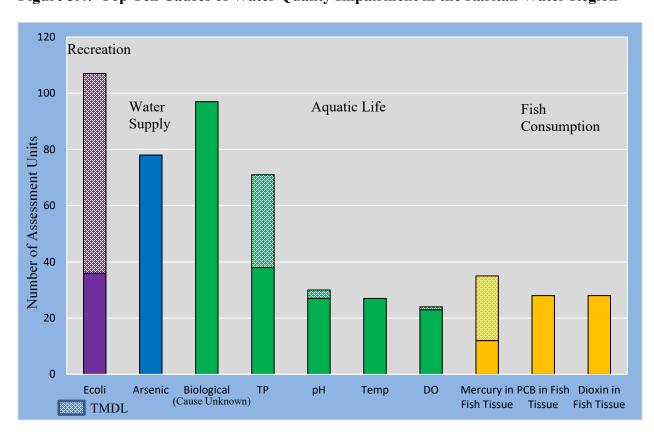

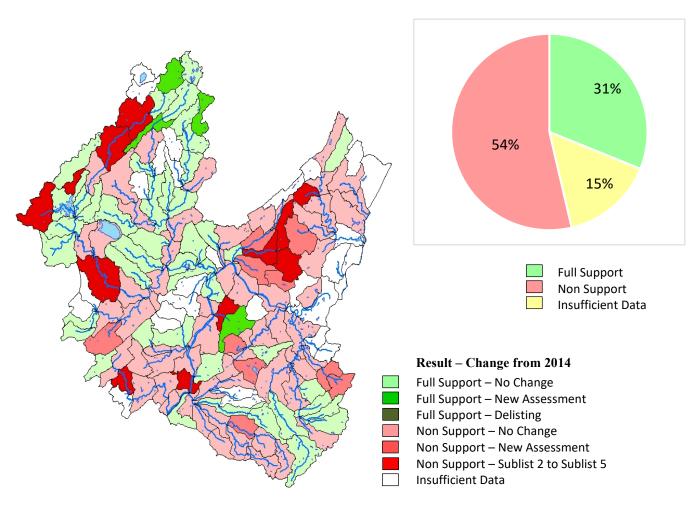

Figure 3.4: Top Ten Causes of Water Quality Impairment in the Raritan Water Region

Assessment results for each designated use are discussed in more detail below, along with results for key parameters associated with each use.

Public Water Supply Use: The public water supply designated use had the highest percentage of supporting watersheds in the Raritan Water Region with 31% of applicable AUs fully supporting the public water supply use, 54% not supporting the use, and 15% with insufficient information to assess the use (see Figures 3.5A and B).

Figure 3.5A: Raritan Water Region Assessment Results for Public Water Supply Use, Spatial Extent

Figure 3.5B: Raritan Water Region Assessment Results for Public Water Supply Use, Percent (%)

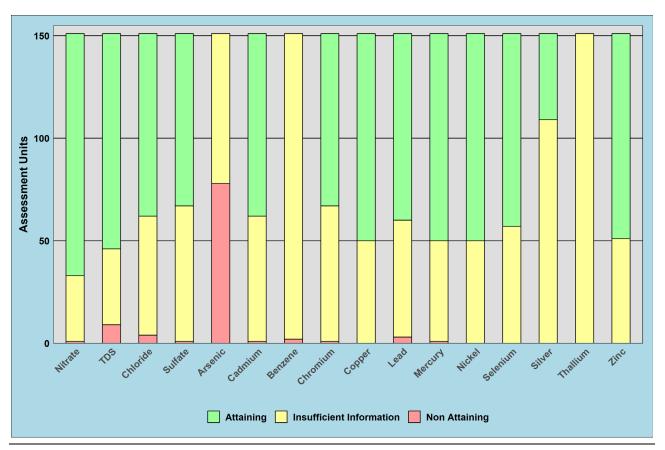

Similar to the rest of the state, the predominant cause of use impairment is arsenic with 96% of impaired AUs exceeding the arsenic human health criteria. ¹⁷ The frequency of arsenic impairment has increased over time due to improved detection of arsenic at levels approaching the human health criterion of 0.017 ug/l. This human health criterion is much more stringent (by more than an

¹⁷ The Department has determined that if aquatic life and public water supply uses are fully supported, then the agricultural and industrial water supply uses are also fully supported (see Section 6.6 of the 2014 Methods Document). As a result, these uses are no longer separately assessed.

order of magnitude) than the New Jersey maximum contaminant level (MCL) of 5 ug/L established in the Safe Drinking Water Act rules at N.J.A.C. 7:10-5.2 (see http://www.nj.gov/dep/rules/rules/njac7_10.pdf). Only two waterbodies in the Raritan Water Region (South Branch Raritan River at Budd Lake, Red Root/Crows Mill Tributary of Lower Raritan River in Edison Township) have detected arsenic concentrations above the drinking water standard of 5 ug/L. Neither of these impaired AUs have surface water drinking water intakes.

A small number of AUs exceeded the human health criterion for other pollutants such as chloride and TDS (see Figure 3.6). New sampling detected chloride exceeding its criteria in Ambrose Brook, East Branch Middle Brook, South Branch Rahway River, and Rahway River. Additionally, TDS exceeded its criteria in these AUs as well as in Elizabeth River, Green Brook, and West Brook Rahway River. All of these watersheds are fully built-out with stormwater contributing a significant load during storm events. Metals predominately attained applicable water quality standards except for arsenic. Where data was sufficient to make an assessment, metals achieved 99% attainment. The only recent metal sampling that detected concentrations exceeding human health criteria entailed lead in the Elizabeth River and benzene in the lower Raritan River mainstem. Legacy impairments in the South River for cadmium, chromium, and mercury requires new sampling to determine current water quality. See Table 3.3 for metal trends since 1998.

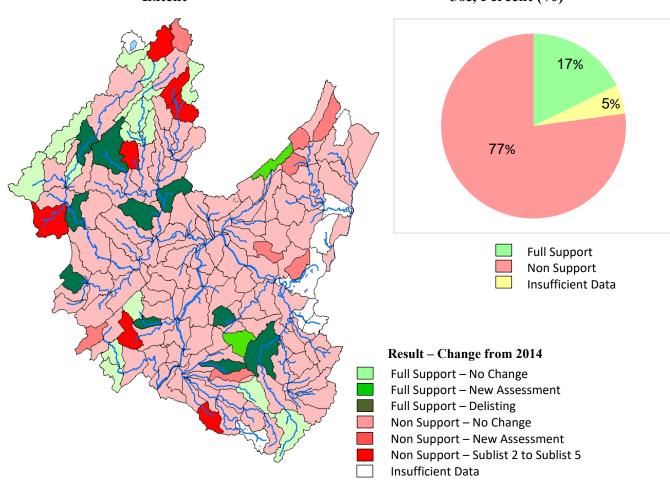

Figure 3.6: Raritan Water Region Assessment Results for Parameters Associated With the Water Supply Use (151 AUs)

General Aquatic Life Use: The Raritan Water Region has the highest percentage of AUs in the state with biological and chemical data required for aquatic life use analysis with only 5% with insufficient data to make an assessment. Seventeen percent of the Raritan's AUs fully support the general aquatic life use while 77% do not support the use. (see Figures 3.7A and B). The predominant parameter reflecting aquatic life use impairment is biological data whose indices reflect impaired communities in 62% of the AUs in the region. The primary pollutants not supporting aquatic life use include total phosphorus, pH, dissolved oxygen, and TSS. (see Figure 3.8).

Figure 3.7A: Raritan Water Region Assessment Results for General Aquatic Life Use, Spatial Extent

Figure 3.7B: Raritan Water Region Assessment Results for General Aquatic Life Use, Percent (%)

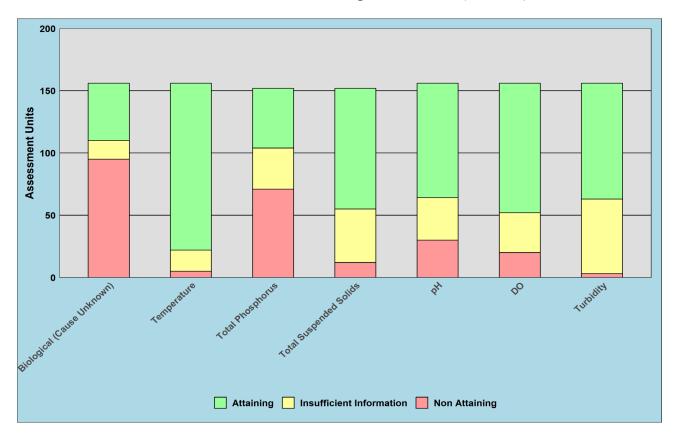

Figure 3.8: Raritan Water Region Assessment Results for Conventional Parameters Associated with the General Aquatic Life Use (156 AUs)

Total phosphorus (TP) attained applicable WQS in 31% of 150 AUs with 47% not supporting and 22% with insufficient information. TP levels in the upper South Branch and North Branch Raritan River were noticeably lower than the rest of the region and demonstrated a high number of AUs fully supporting. These watersheds are characterized as having significant number of areas with undeveloped land use with healthy riparian zones. Areas downstream including the Millstone, Lower Raritan River, and Arthur Kill are impacted by a much greater share of agricultural land use, urban development, and wastewater treatment plants that are contributing to the higher TP levels. The Raritan TMDL addresses over 45% of the impaired AUs for TP.

pH attained applicable WQS in 60% of all AUs, 19% exceed criteria, and 21% have insufficient information. pH impairments are found scattered throughout the region. Most of these impairments are associated with high nutrient levels and it is expected that pH levels will respond to restoration efforts aimed at controlling nutrients. The Raritan TMDL addresses over 10% of the impaired AUs for pH.

Dissolved oxygen (DO) attained applicable WQS in 68% of all Raritan AUs, 12% did not attain, and 19% had insufficient information. Healthy DO levels were achieved throughout the region with the majority of exceedances focusing in the upper Millstone River and upper tributaries to South

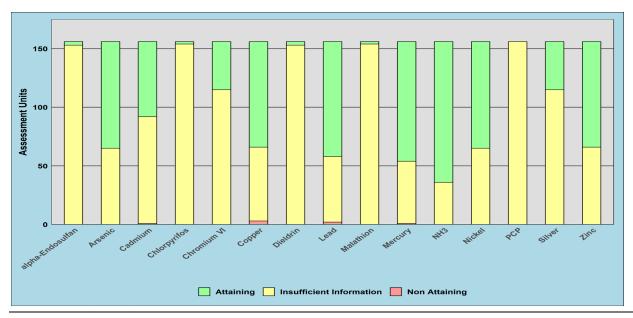

River located in the Coastal Plain physiographic region. It is likely that these low DO levels are due to high nutrient loads along with the significant input of ground water that may have low oxygen levels coupled with the slow, meandering flow, and adjacent wetlands which naturally reduces stream aeration.

Temperature shows very high attainment rates throughout the region, with 87% of all Raritan AUs attaining applicable WQS, 3% exceeding the criteria, and 10% with insufficient information. The exceedances of the temperature criteria were almost exclusively in the lower Raritan River mainstem from below the confluence with the North Branch and South Branch to the tidal portion of the river. The waterway is characterized as predominately urban land use with highly degraded riparian zones, and a wide river channel that lead to rapid rises to water temperature.

Total suspended solids (TSS) attained applicable WQS in 65% of all AUs, 8% did not attain, and 27% had insufficient information. **Turbidity** attained applicable WQS in 60%, 2% did not attain, and 38% had insufficient information. As with temperature, the majority of exceedances occurred in the lower Raritan River mainstem from below the confluence with the North and South Branch Raritan to the tidal portion of the river, but there were pockets in the North and South Branch that also exceeded the criteria. The Raritan TMDL addresses 67% of the impaired AUs for TSS.

Metals predominately attained the aquatic life use criteria, except for new sampling that detected exceedances in the Elizabeth River and Red Root Creek/Crows Mill Creek for cooper and lead respectively (see Figure 3.9). Where data was sufficient to make an assessment, metals achieved 99% attainment. Legacy impairments in the South River for cadmium, chromium, copper, lead and mercury requires new sampling to determine current water quality. See Table 3.3 for metal trends since 1998.

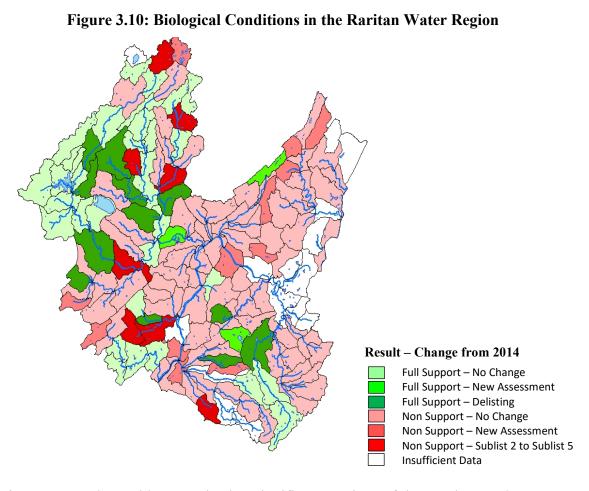

Figure 3.9: Raritan Assessment Results for Metal and Toxin Parameters Associated with Aquatic Life Criteria (156 AUs)

Biological Conditions

Biological monitoring in the Raritan Water Region is the most extensive in the entire state with over 92% of AUs having biological data compared to 59% statewide. Overall biological conditions show that 30% are fully supporting, 62% are not supporting and 8% have insufficient data. Although the biota in the region reflect extensive impairment, there are large areas where biological communities are healthy and fully supporting uses mostly focused in the Upper Raritan River, Stony Brook and Manalapan Brook watersheds. Biological conditions seem to be correlated to land use in the watershed and impacts from point sources. The Arthur Kill watershed (WMA 07) showed the most extensive non support with all of the AUs with data showing impairment. The watershed is nearly 100% urban with numerous major dischargers located within this WMA.

Unlike the other three WMAs, the Upper Raritan (WMA 08)exhibits healthy biological communities most of its AUs. The South Branch Raritan River has the healthiest biological communities with impairments focusing in the lower watershed where extensive land agriculture use in the Neshanic River watershed as well suburban as development in the other watersheds are impacted by storm

water, degraded riparian zones, and unstable streambanks. Significant portions of the North Branch Raritan system are in non-attainment with sources believed to be contributing to impairment include suburban development, point source discharges, storm water, and agriculture. The Lamington River and Rockaway Creek watersheds are exhibiting healthy biological communities with the Rockaway Creek showing significant improvements in this cycle.

The Lower Raritan (WMA 09) exhibits extensive areas of non-attainment. Manalapan Brook has been assessed as the only watershed within this WMA as fully supporting biota communities. The remainder of the WMA shows extensive urban/suburban development, heavy commercial/industrial development, point sources, and limited agriculture. The extensive wetlands in the WMA may have a negative effect on local stream biota through the release of poorly oxygenated water in some locations.

The Millstone River (WMA 10) is also characterized by extensive regions exhibiting biological impairment. Stony Brook had the healthiest biological conditions with other watersheds assessed as healthy limited to their headwaters. WMA 10 is a complex of urban/suburban development, agriculture with some wetlands. The extensive impairments are attributed to urbanization and agriculture with its accompanying disruption of habitat and riparian zones, stormwater, and unstable streambanks.

Characteristics of Streams and the Impact on Biota

An analysis where biota reflect full support show they are located in watersheds with healthy, forested riparian zones that include wetlands. Riparian areas are transitional areas between terrestrial and aquatic ecosystems that are vital to watershed health. In watersheds with agricultural use or anthropogenic disturbance such as industrial, commercial, and residential development, the riparian zone provides a buffering between the stream and the area of disturbance. These buffers demonstrate that they help to preserve the stream channels and habitat in their natural condition.

It is important to understand the importance of forested canopies and riparian buffers to preserve and maintain stream ecological integrity. As discussed in Giller and Malmqvist (2001)¹⁸, forested buffers have substantial and positive influences on stream ecology. The overlying canopy, moderates water temperature by providing shade to protect against solar radiation and high daytime

air temperatures. Additionally, the cooler waters enhance oxygen carrying capacity in the water column which is especially critical in trout waters and limits primary production thereby limiting the impact of excessive nutrient inputs. A healthy riparian zone reduces stormwater runoff and pollutants such as nutrients, toxics and pesticides from sources in the watershed before they enter the stream. Forested buffers stabilize the streambank reducing erosion and siltation while the exposed root systems within the stream provide hiding places for fish. The leaf and woody debris become an important source of nutrients and carbon to the

aquatic system. The leaf litter and woody debris that accumulate on the stream bottom provide a diverse range of habitat for invertebrates and fish as well as refuge from stream flow. Additionally,

¹⁸ Giller P., and Malmqvist B., 2001. The Biology of Streams and Rivers. Oxford University Press. Pp. 33, 37-38.

the buildup of woody material can form debris dams influencing flow patterns, causing the formation of pools and eddies thereby enhancing habitat diversity within the stream channel.

An analysis of how land use impacts the aquatic ecosystem was completed by observing the land use in riparian zones, defined as 300-foot buffers around the streams, as well as, land use in the whole AU. For the assessment, the extent of land use in the AUs and their riparian zones was calculated for "developed" land use defined as urban, suburban, and agricultural land use; "undeveloped" land use which includes forest, wetlands, and the waterways; and impervious surface. Numerous studies have shown that of all of the land use indicators, impervious surface is the most predictive and reliable indicator for biological integrity ¹⁹. The studies reveal that where impervious surface exceeds 10% of watershed land use biological degradation occurs.

As with previous studies, in the Raritan Water Region impervious surface shows it is the most predictive and reliable indicator for biological integrity compared to developed and undeveloped land use. Land use shows that when impervious surface exceeds 10% in an AU then only 24% of the AUs have healthy biological communities. In watersheds with less than 10% impervious surface, the percent of healthy biological communities rises to 66%. Developed AUs with high impervious surface will overwhelmingly display impaired biological communities although an intact riparian zone can mitigate some impacts on the biota. Meanwhile an AU with less than 10% impervious surface exhibits the highest probability for healthy biological communities. Low impervious surface and a healthy riparian zone is associated with healthy biological communities. Where impervious surface is low, impairments primarily occur where agricultural land use is high causing degradation to the function of the riparian zone.

When observing impervious surface in riparian zones, the riparian buffer exhibits very high sensitivity to land use changes in the watershed. Where impervious surface exceeds 10% in the riparian zone, the biological communities display extensive degradation with 90% of the biological communities impaired. Without a buffer to reduce the effects of stressors within the watershed, the biological communities are inundated and unable to recover. Development in the riparian zone degrades the benefits from a healthy ecosystem by intensifying storm water flow, destabilizes streambanks, increases levels of sedimentation and other nonpoint pollutants, rises water temperatures, damages stream habitat, reduces infiltration into the soil, as well as increases the frequency and intensity of flooding and low stream flows.

New Jersey's water quality protection programs guard against further degradation of the State's waters in part through protection of riparian buffers. These protections include the SWQS antidegradation policies that provide special riparian protection to Category One (C1) waters based on their exceptional ecological significance, exceptional water supply, exceptional recreation and exceptional fisheries to protect and maintain their water quality, aesthetic value, and ecological integrity²⁰. These waters are afforded 300-foot development buffers under the Flood Hazard Area Control Act (N.J.A.C. 7:13) and along with the Stormwater Management Act rule (N.J.A.C. 7:8) regulate certain activities proposed within or impacting riparian zones to help maintain the water quality functions of the buffers. Additional information on these rules and associated programs are available the Department's web site at http://www.nj.gov/dep/landuse http://www.nj.gov/dep/stormwater.

Impaired Bio Community

Healthy Bio Community

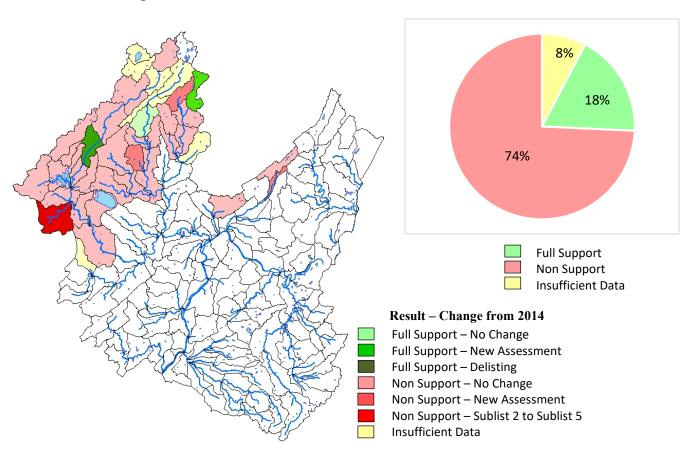

Figure 3.11B: Biological Community vs Riparian Zone Developed Land Use and Impervious Surface

0%

Trout Aquatic Life Use: Trout waters within the region are limited to the North and South Branch Raritan River and headwaters of Green Brook and Middle Brook. Overall, 8% of the applicable AUs fully support the use, 74% do not support the use, and 18% have insufficient information to assess the use (see Figures 3.12A and B). AUs with trout waters are characterized as having higher quality waters which consists of higher DO levels and lower water temperatures than general aquatic life use.

Figure 3.12A: Raritan Water Region Assessment Results for Trout Aquatic Life Use, Spatial Extent

Figure 3.12B: Raritan Water Region Assessment Results for Trout Aquatic Life Use, Percent (%)

Temperature was the most frequent causes of trout use impairment, showing non support in 59% of applicable Raritan AUs (see Figure 3.13). Extensive continuous monitoring for temperature has consistently detected exceedances during the diurnal cycle that was not always captured with discrete monitoring. Where data was available, 82% exceeded trout temperature criteria whereas for DO, continuous monitoring indicated healthy oxygen levels with only 16% exceeding trout DO criteria. During the development of the Raritan TP TMDLs, the Department found that a number of AUs considered to be impaired by temperature might actually reflect natural conditions. A more indepth analysis of these impaired AUs is underway to determine if temperature reflects natural conditions or actual use impairment. Biological communities in trout waters are significantly higher quality with 72% fully attaining compared to only 30% fully attaining regionwide. During this

cycle, biota improvements occurred in Rockaway Creek, Beavers Brook and along South Branch Raritan River in Lebanon Township. Other pollutants that impacted aquatic life use for trout included TP with 18% impaired, pH with 18% impaired and TSS with only 8% impaired. Metal monitoring indicated no exceedances of the aquatic life criteria in trout waters (see Fig 3.13B).

Figure 3.13: Raritan Water Region Assessment Results for Conventional Parameters Associated with the Trout Aquatic Life Use (39 AUs)

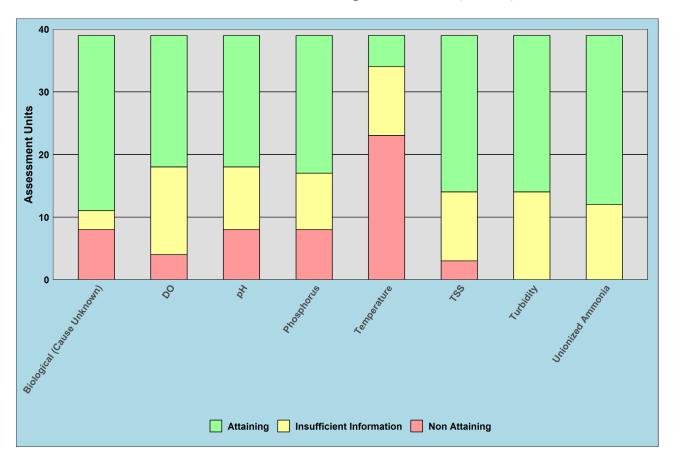

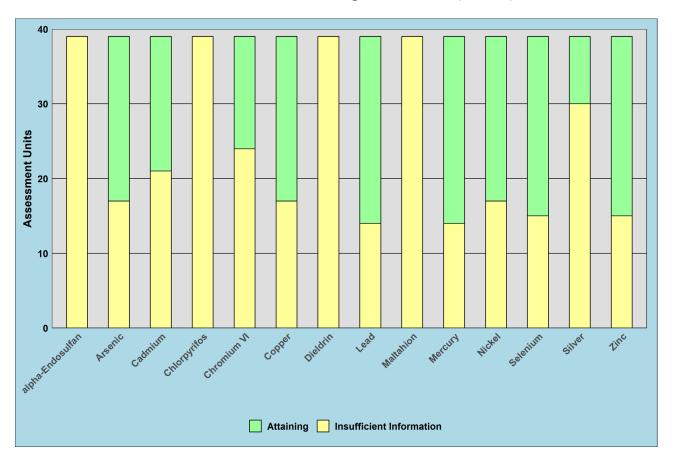

Figure 3.13B: Raritan Water Region Assessment Results for Metal and Toxin Parameters Associated with the Trout Aquatic Life Use (39 AUs)

Recreation: As shown in Figures 3.14A and B, 12% of Raritan's AUs fully support the recreational use, 70% do not support the use, and 18% have insufficient information to assess the use. Monitoring throughout the region has detected *E. coli* levels that consistently exceed recreational criteria with only a few small pockets where criteria is met. In many areas, pathogen levels increase dramatically during rainfall events, indicating stormwater runoff (nonpoint sources of pollution) as the source of these pollutants. These sources may be from human, pet, livestock, or wildlife waste. Common causes of high *E. coli* levels include stormwater runoff, septic system failures, illicit sewer system connections, livestock, manure storage facilities, agricultural lands that receive manure applications, wildlife including geese, and resuspension from sediments.

Figure 3.14A: Raritan Water Region Assessment Results for Recreation Use, Spatial Extent

Figure 3.14B: Raritan Water Region Assessment Results for Recreation Use, Percent (%)

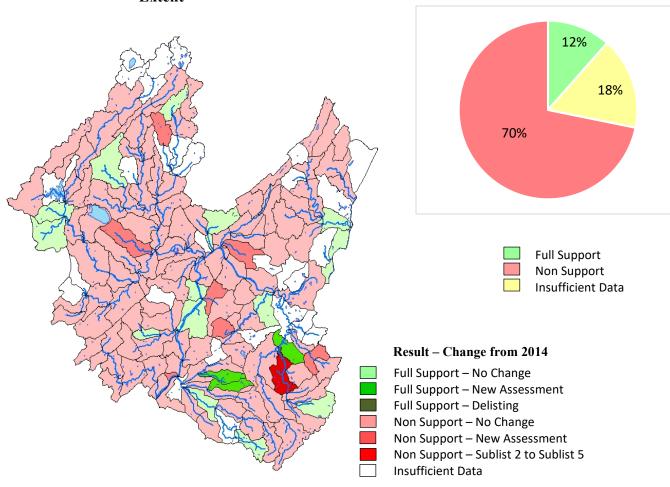

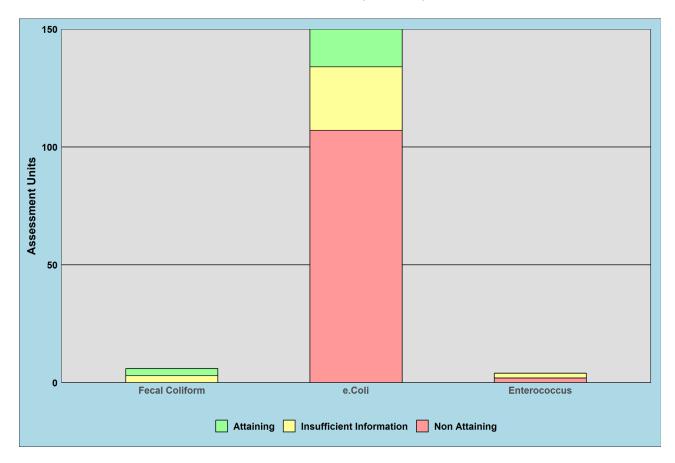

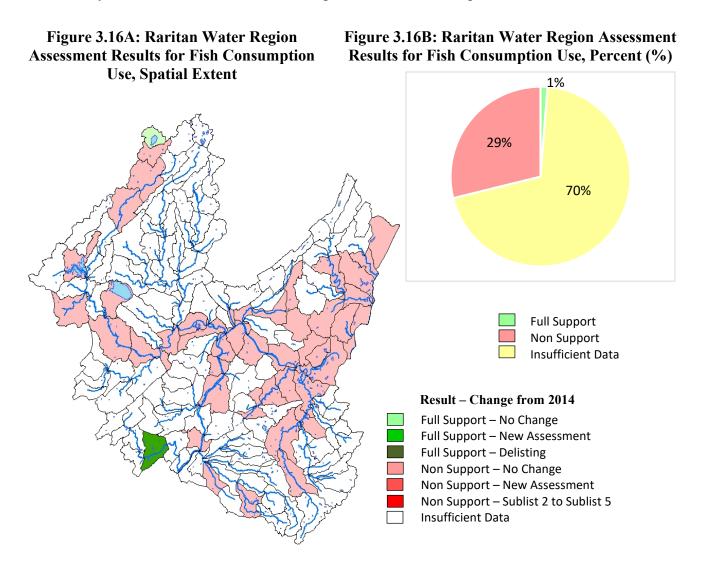

Figure 3.15: Raritan Water Region Assessment Results for Parameters Associated with the Recreation Use (156 AUs)

Fish Consumption: The fish consumption use is assessed based on bioaccumulative toxins that are used to develop fish consumption advisories. Only two of Raritan's AUs fully support the fish consumption use; however, 70% of AUs have insufficient information to assess the use, primarily due to a lack of fish tissue data (see Figures 3.16A and B). Where data is available, they show that 96% of the AUs are impaired for fish consumption.

"Legacy" pollutants such as PCB, chlordane, DDT, dieldrin, and heptachlor epoxide are no longer manufactured but collectively comprise a majority of the consumption restrictions. Although the data is predominately detecting toxins in fish tissue that prohibits unrestricted fish consumption, some new data did reveal several areas within the region where toxins have decreased and levels meet unrestricted fish consumption. The following waterbodies met their criteria: Rosedale Lake (Stony Brook) for mercury, PCB, chlordane and DDT; Manalapan Lake for mercury; Round Valley Reservoir for chlordane and DDT; Davidsons Mill Pond (Lawrence River) for chlordane; and Weston Mill Pond (Lawrence River) and lower Raritan River at Route 1 (tidal portion) for DDT.

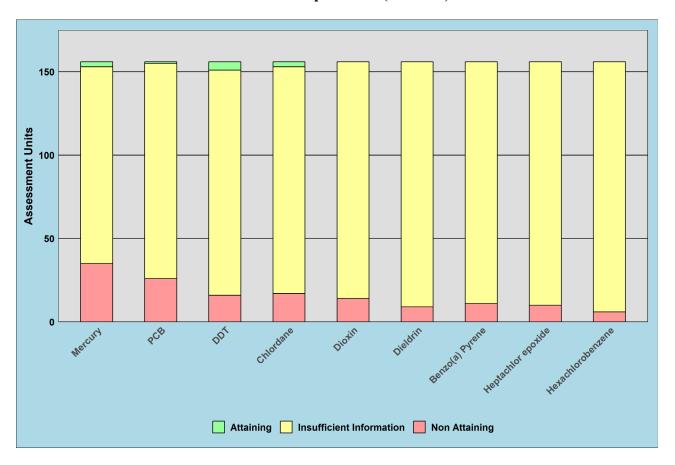

Figure 3.17: Raritan Water Region Assessment Results for Parameters Associated with the Fish Consumption Use (293 AUs)

Shellfish Harvest for Consumption: Shellfish harvesting is only applicable to two AUs in the Raritan Water Region, Raritan River below South River and Red Root Creek/Crows Mill Creek. Data for the Raritan River shows pathogen levels that prohibit shellfish harvesting while the creeks do not have data.

Trends in the Raritan Water Region

Nutrient Trends

Nutrient data from five monitoring sites distributed through the region were analyzed by a Weighted Regressions on Time, Discharge, and Season model (WRDTS) using data from 1988 to 2011 as part of the USGS statewide trends analysis. As with statewide trends, nutrient trends in the Raritan Water Region show improving or stable conditions. TN demonstrates the best conditions with decreasing or stable trends at all sites. TP displayed stable conditions with all stations showing no trends. Nitrate and nitrite trends display improving and stable conditions except in the Lower Raritan River in Bound Brook where there is an increasing trend. Although nitrate and nitrite levels

are increasing, current levels are well below applicable water quality criteria and do not expect to exceed the criteria in the near future.

The improving and stable nutrient conditions in the region can be attributed to the upgrades to wastewater treatment, the implementation of statewide nonpoint source management efforts, and land use changes over the time period. As explained in Section 2.3, the late 1980s and 1990s saw a significant upgrade in sanitary treatment quality where wastewater treatment plants were required to upgrade to secondary treatment. Secondary treatment required additional treatment to remove organic compounds by biological processes that lowered nutrient levels. Additionally, smaller primary plants were regionalized into larger more efficient secondary plants resulting in the removal of the smaller inefficient primary plants from the region. Additionally, nonpoint source controls began to expand in the late 1990's with the implementation of the MS4 and Nonpoint Source Permitting Programs.

Land use changes since the 1980's has shown significant urban development throughout the region. Since 1986, urban land use has increased over 35%, however, nutrient levels have not shown a corresponding increase expected from development in the watershed. Urbanization increases impervious surfaces of the land due to the building of roads, pavement, and rooftops which cause rain and snowmelt to remain on the surface. The nonpoint source runoff then moves over the land and picks up natural and human-made pollutants depositing them into lakes, rivers, wetlands, ground and coastal waters. These include:

- Excess fertilizers, herbicides, and insecticides from agricultural and residential areas;
- Oil, grease, and toxic chemicals from vehicles, urban and developed land and industrial facilities;
- Sediment from improperly managed construction sites and other disturbed land uses;
- Excess salt from winter road management;
- Bacteria and nutrients from livestock, pet wastes, and faulty septic systems;
- Atmospheric deposition; and
- Consequences of hydromodification, such as bank and channel erosion.

In order to explain the stabilization of nutrients in the region, an analysis of the land use data reveals that the majority of the urban development has occurred on agricultural lands and not on undeveloped wetland or forested lands. This has caused a stabilizing effect by replacing nutrient runoff from agricultural practices to inputs from less intensive domestic activities such as fertilizing of lawns. Although the region has experienced declines in forested land by 5% and wetlands by 10%, the development on agricultural lands, 35% decline, has helped protect the benefits from the undeveloped land use in stabilizing nutrient inputs into the region's waterbodies. Forested lands and wetlands provide many benefits to water quality, especially in the riparian zone, by decreasing storm water runoff, increasing infiltration rates, filtering out pollutants, providing shading to moderate temperatures, increasing oxygen levels, and limiting primary production from excessive nutrients.

Increases of nitrate levels in the Lower Raritan River are likely attributed to upgrades to treatment plants upstream to reduce ammonia which can lead to increases of its oxidized forms. As discussed earlier, decreases of ammonia are often accompanied by increases in nitrate as treatment plants

oxidize the ammonia to eliminate it. Ammonia is more deleterious to the environment than the more oxidized species of nitrogen through its uptake of oxygen and its toxicity to aquatic life.

Biological Condition Trends

Biological trends in the Raritan Water Region were determined by reviewing the index categories for benthic macroinvertebrates and fish communities between 1999 to 2015. Overall, both fish and macroinvertebrate trend assessments point to stable conditions in the Raritan Water Region with the majority of sites showing no changes over the 15-year period. However, there was an observable trend in the number of "Excellent" conditions and "Poor" conditions migrating toward the "Good" and "Fair" categories.

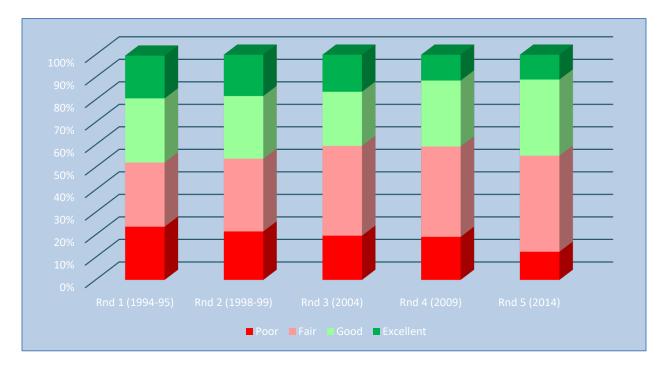

Figure 3.18: Biological Trends in Raritan Water Region from 1999 to 2015

The reduction in the number of "Poor" sites predominately occurred in urban watersheds in the lower Raritan Water Region including the Millstone River watershed where heavily impacted watersheds have shown modest improvements. The declining number of "Excellent" sites have exclusively been limited to WMA 8 in the Upper Raritan which has the highest rate of urbanization over the last few decades.

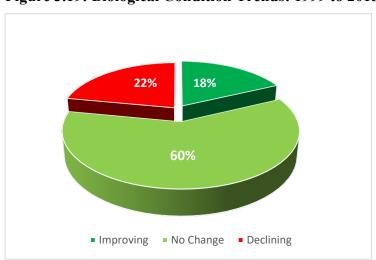

Figure 3.19: Biological Condition Trends: 1999 to 2015

Regarding biological sites assessed as showing "no change," many benthic macroinvertebrate communities displayed high variability through the assessment period, alternating up and down between "Good" and "Fair" conditions without ever showing any trend direction. Such sites are labeled as "mixed" and represented almost half of the AMNET sites assessed as exhibiting "no change." These sites are impacted by anthropogenic sources, but depending on the season and varying local conditions (e.g. temperature, rainfall,

storm flow, or nearby activities) these sites oscillate in a mediocre state between "Good" and "Fair."

During the last few decades, urbanization in the region has increased significantly. Although the replacement of agricultural lands with urban/suburban land use has had a stabilizing effect for chemical loads, the increase of impervious surface has impacted the biological communities. A review of land use changes in the AUs between 1995 and 2012 show urban land use replacing agricultural land with minimal loss of forest and wetlands. At benthic macroinvertebrate monitoring sites that show declining index scores, median increases of urban land use changes are 10% with impervious surface increasing by 6%, and losses of only 2% of forested land and 1% of wetlands. At monitoring sites that show improving or fully attaining index scores, median changes show urban land use increasing by 5% with impervious surface only increasing by 2.5%, and forested land use declining by 2% and wetlands by 0.5%. Declining macroinvertebrate sites show significant increases of impervious surface over the time period compared to improving and fully supporting stable sites. The replacement of pervious land with impervious surfaces increases storm water and the associated impacts such as degraded riparian zones, unstable streambanks, higher turbidity, nutrients, erosion, and other chemicals flowing into the water bodies.

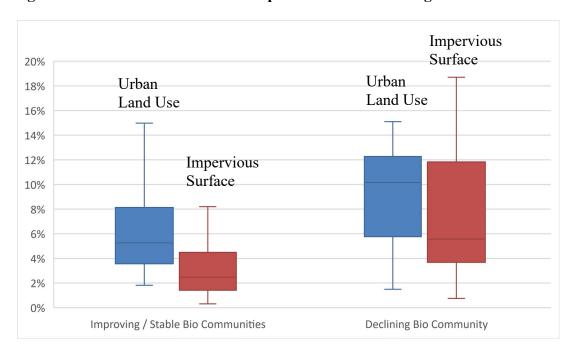

Figure 3.20: Urban Land Use and Impervious Surface Changes from 1995 to 2012

Metals and Ammonia Trends

The most remarkable development in the Raritan Water Region is the dramatic decrease of metal and ammonia levels in the region resulting in a 95% decrease in the number of impairments on the 303(d) List since 1998. This does not include arsenic which continues to be detected at levels that exceed the human health criteria. In 1998, there were 191 303(d) listings for metals including unionized ammonia. Years of monitoring has revealed only nine 303(d) listings for metals remain in 2016. This remarkable improvement is the result of rules and regulations that have limited the

discharge of toxins in the waterways and air, the remediation of contaminated sites, and the closing or shifting of many manufacturers out of the region. Statewide metals and toxins discharging into waterbodies have drastically been reduced, however, legacy issues still impact some areas of the state where metals remain in the sediment. During storms and high flow, these sediments can become resuspended in the water column and elevated metal levels can be found exceeding their criteria. In the Raritan Water Region, metal levels remain low even during high flow events indicating clean sediment and/or metals that are buried to far below the sediment to be resuspended. Declines of ammonia levels are attributed to improved wastewater treatment processes that have resulted in reduced discharge levels.

While metal and toxin levels have declined significantly in the Raritan Water Region, recent sampling indicates a few exceptions where criteria are exceeded such as copper in the Elizabeth River, benzene in the Lower Raritan River, and lead in a tributary (Red Root/Crows Mill Creek) of the Lower Raritan River. South River originally listed on the 1998 303(d) List continues to be listed and requires new sampling to determine current water quality conditions.

Arsenic was not incorporated into this trend assessment. The frequency of arsenic impairment has increased over time due to improved detection of arsenic. This human health criterion is much more stringent (by more than an order of magnitude) than the New Jersey drinking water standard of 5 ug/L established in the Safe Drinking Water Act rules at N.J.A.C. 7:10-5.2 (see http://www.nj.gov/dep/rules/rules/njac7 10.pdf). Only a couple of waterbodies in the Raritan Water Region (South Branch Raritan River below Budd Lake and Red Root Creek) have detected arsenic concentrations above 5 ug/L yet most exceed the SWQS human health criterion. Neither of these waterbodies are in proximity to any surface water drinking water intakes.

3.4 - Actions Addressing Key Water Quality Concerns

Over the last 10 years the Department has focused a strategy that allocated the resources needed to increase monitoring that has successfully reduced data gaps and achieved a stronger understanding of water quality conditions in the region. With this understanding of water quality issues in the Raritan Water Region, the Department has been able to initiate management actions to protect, maintain, and restore water quality. Several significant efforts in the Raritan Water Region including the approval of the Raritan TMDL, the Raritan Protection Plan, and the nonpoint restoration efforts described in this section. These actions along with future efforts are expected to reduce pollutant loading to help restore water quality. It is not expected that results will occur quickly, but by addressing point source, nonpoint source, and minimizing impacts from future development, water quality can be improved and designated uses restored over time.

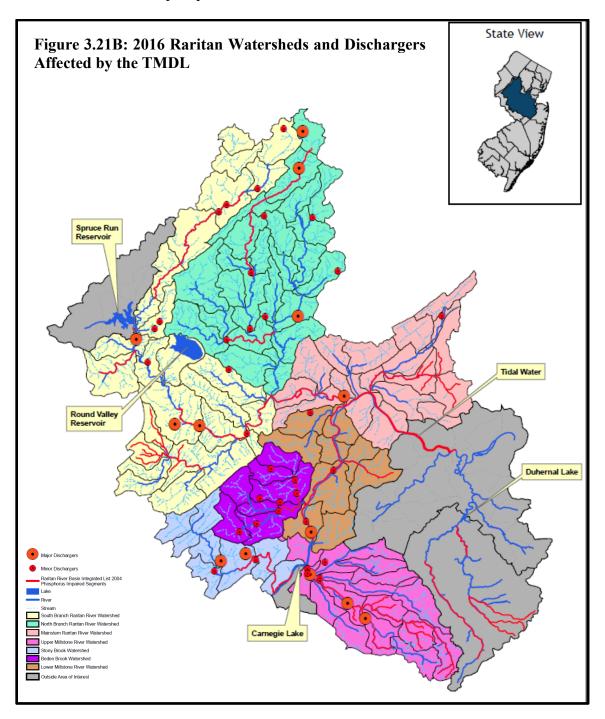

Raritan TMDL

In May 2016, EPA approved "Total Maximum Daily Load Report for the Non-Tidal Raritan River Basin Addressing Total Phosphorus, Dissolved Oxygen, pH and Total Suspended Solids Impairments." The TMDL Report addresses 33 Total Phosphorus (TP), 3 pH, 1 Dissolved Oxygen (DO), and 15 Total Suspended Solids (TSS) impairments (see Figure 3.21). This has been arguably the most significant management action in the Raritan Region Water address impairments to water quality. The TMDL study area includes the North and South Branch Raritan River, Upper Millstone River, Stony Brook, Lower Millstone River, Bedens Brook, and the Mainstem Raritan River Fieldville Dam. The watersheds of the Spruce Run Reservoir, Round Valley Reservoir, and Delaware and Raritan Canal were not modeled as part of this study. It was determined that addressing TP impairments along the mainstem Lower Millstone River and the

Figure 3.21: Raritan TMDL for TP, TDS, pH, and DO

mainstem Raritan River between the Millstone River confluence and Fieldville Dam was deferred pending further study. In addition, the Duhernal Lake will be the subject of a separate forthcoming TMDL to address total phosphorus.

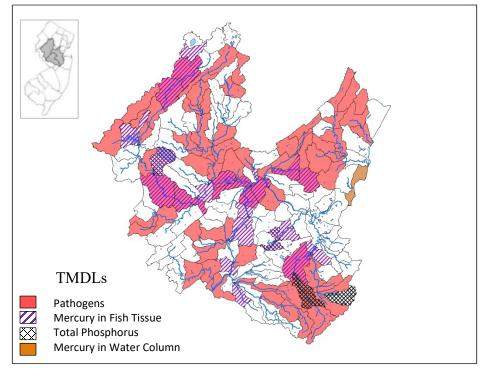

A TMDL implementation plan was developed to identify the suite of measures that are needed to reduce loads from each source to levels that will meet surface water quality standards. Regulatory measures typically include effluent limitations or additional measures that are incorporated into

wastewater or stormwater permits issued pursuant to the New Jersey Pollutant Discharge Elimination System (NJPDES). The Raritan TMDL affects 45 wastewater treatment plants (WWTPs) located in the study area. The WWTPs are subject to TMDL specified TP and/or TSS restrictions. Total phosphorus limitation will be required for 38 WWTPs. The current condition in the watershed area was calculated to equal 456.9 kilograms/day (kg/d) of TP and 61,266 kg/d of TSS. The TMDL condition would reduce the pollutant load to 243.4 kg/d of TP and 38,641 kg/d of TSS. Through these collective actions and continued dedication of local stakeholders, the Department expects to achieve the reduced loading from regulated stormwater and NPS needed to attain water quality standards.

Other TMDLS

Previous to the Raritan TMDL, the Department completed 104 TMDLs addressing pathogens for recreational use, phosphorus for aquatic life use, and mercury in fish tissue and mercury in the water column for fish consumption. These **TMDLs** located throughout the region are depicted in Figure 3.22. The majority of TMDLs address pathogens covers 72 AUs followed by mercury in fish tissue with 25 AUs, total phosphorus with four AUs and mercury in fish tissue

Figure 3.22: Other TMDLs Approved in Raritan Water Region

in one AU. Additional information on these AUs and the Raritan TMDL can be found on the website: https://www.state.nj.us/dep/wms/bears/tmdls.html.

Raritan Protection Plan

As the first state in the nation to develop and receive EPA acknowledgement for a watershed protection plan, the *Non-tidal Raritan River Watershed Protection Plan (WPP)* brings together the many ongoing and newest water quality restoration actions being implemented in the Raritan to protect unimpaired waters while restoring impaired waters in this watershed. The WPP is based on the data and modeling results generated for the *Total Maximum Daily Load Report for the Non-Tidal Raritan River Basin*. Assessment units covered by this protection plan include those that attain the SWQS for total phosphorus and/or total suspended solids on the 2014 Integrated List and are within the area covered by the non-tidal Raritan River TMDL study. A total of 90 separate

AU/parameter combinations in 66 separate AUs are identified for protection through the WPP with 36 AUs protected for TSS; six for TP and 24 for both TSS and TP.

The WPP reflects a watershed approach that is based on the implementation of the Raritan TMDL which will provide a benefit to unimpaired HUCs within the watershed. Furthermore, a full complement of regulations, funding, and stewardship partnerships implemented through regulatory and nonregulatory approaches are key to protect and restore water quality. In order to ensure future water quality protection and restoration, the continuation of nonpoint source restoration projects, water quality monitoring, and stakeholder involvement are essential for the success of the plan. Restoration efforts to date have helped improve water quality in the region resulting in delisting five AU/parameter combinations that were previously on the 303(d) list of impaired waterbodies. The WPP aims to expand upon these positive results and achieve the Department's goal of restoration, maintenance and preservation of water quality in the Raritan River watershed.

Nonpoint Restoration Activities

Addressing nonpoint sources is a critical piece in the restoration efforts in the region. Many of the waters placed on the 303(d) List are impaired primarily by nonpoint sources of pollution and regulated stormwater sources. For these impairments, development of a <u>watershed restoration plan</u>

or watershed based plan (WBP) can be an effective alternative to a formal TMDL to characterize pollutant sources, the reductions needed to attain standards, and the means to achieve the reductions. When adopted as an amendment under the Water Quality Management Planning rules, a WBP can be implemented using measures such as those that would appear in a TMDL implementation plan (refer to N.J.A.C. 7:15-5.25(g)). The Department is pursuing this approach for 303(d) Listed waters where stormwater and nonpoint sources of pollution are believed to be the predominant source of water quality impairment.

Previous Department funding prioritized the development of 9-element WBPs in accordance with EPA guidance. As a result, the Department has approved WBPs in locations throughout the State including seven WBPs covering 13 AUs in the Raritan Water Region. A WBP identifies strategies to reduce the loads of pollutants of concern to attain Surface Water Quality Standards. Implementation of these WBPs is expected to improve water quality without the need for a TMDL. The WBP load reduction measures depend largely on actions that could be accomplished using 319(h), Farm Bill and other funding sources and stewardship activities. Therefore, in locations where the sources are nonpoint or stormwater in nature and non-regulatory measures are the primary means available to reduce the loads, the Department will opt to pursue restoration and stewardship building actions directly as the preferred path to reduce loads and attain water quality standards. Additional information regarding developing a nine-element watershed based plan is available from USEPA's Handbook for Developing Watershed Plans to Restore and Protect Our website https://www.epa.gov/sites/production/files/2015-Waters the at 09/documents/2008 04 18 nps watershed handbook handbook-2.pdf.

Because nonpoint source pollution diffuses throughout a watershed controlling it is most effective at the source is diffuse, control is most effective at the source. Source control strategies prevent the introduction of pollutants to the environment as well as utilizes natural systems to filter pollutants in the watershed. Strategies include those that resolve existing and past practices, and those that ensure best management practices are applied from the outset. New Jersey's strategies include regulatory, non-regulatory and targeted funding components to address NPS pollution. These strategies include: NJ Fertilizer Law, NJ Stormwater Management Rule, Coastal Zone Management Rules, NJ Flood Hazard Areas Control Act Rule, Water Quality Management Planning Rules, Long Term Control Plans for CSOs, Low Impact Development, NJ Pollutant Discharge Elimination System Rules, Animal Waste Management, contamination remediation, green infrastructure measures, and restoration activities.

Water quality restoration grants are awarded by the Department to fund watershed restoration activities and initiatives that address nonpoint source pollution. Funding sources include USEPA pass-through grants issued under Section 319(h) of the federal Clean Water Act (CWA), Natural Resource Damages (NRD) recoveries, Corporate Business Tax (CBT) funds as well as other federal and State funds that may be available for NPS-related water quality restoration activities. Generally, grants are focused on restoring priority water bodies impaired predominantly by nonpoint source pollution where the grant will help implement an approved TMDL or WBP.

Since 1998, the Department has funded over 65 nonpoint source restoration projects in the region totaling over \$11 million. These projects have included WPB development, streambank restoration,

riparian buffer restoration, lake restoration, livestock control, stormwater controls including detention basin retrofits, agricultural and urban green infrastructure, impervious surface, and manufactured treatment devices. Recent efforts to prioritize restoration efforts in the Raritan Water Region has resulted in \$7.6 million for new projects since 2015 (see Table 3.4).

Table 3.4. Recent NJDEP Funded Nonpoint Restoration Projects in the Raritan Water Region 2015-2017.

| Project Name | Funding | Waterbody | Parameters Addressed | Project Description | Year |
|---|-------------|---|--|---|------|
| Implementation of the Raritan River TMDL | \$700,000 | Raritan River (North, South, Lower); 69 HUC's in 54 Municipalities | Pathogens, TSS, nutrients and floatables | Install green infrastructure in 54 municipalities via plans developed from Sandy NFWF DOI grant | 2015 |
| Implementation of Agricultural and Other BMPs in the Neshanic Watershed | \$1,295,000 | Neshanic River | Phosphorus, TSS | Continue the implementation and construction of agricultural and stormwater BMPs | 2016 |
| Continue to Implement Manalapan WBP | \$450,000 | Manalapan Brook | TP | Design and construction of a roadside WQ swale, covert dry stormwater basin to wetland basin, treatment train at Thompson Park zoo | 2017 |
| Restoration of Beden Brook | \$400,000 | Beden Brook/Raritan | TSS, TP | Implementation of various GI stormwater BMP's in 4 locations in the Borough of Hopewell | 2017 |
| Implementation of Green Infrastructure on Brownfield site in Perth Amboy | \$4,000,000 | Raritan River/Bay | CSO discharge reduction | Implementation of GI on Brownfield site in Perth Amboy | 2017 |
| Raritan Agriculture Mini- Grants | \$145,000 | Mulhockaway Creek, Sidney Brook, Neshanic, Raritan | TSS, TP, Pathogens | Implementation of an agricultural mini-grant program in the Raritan Basin | 2017 |
| Stormwater Basin Retrofits Phase 1 in Franklin Twp. | \$600,000 | D&R Canal/Raritan River | TSS, TP | Implementation of 5 stormwater basin retrofits at the municipal complex, Laird Terrace, Renoir Way, Gauguin Way and Dell Lane, riparian buffer at Cedar Grove Brook | 2017 |

A number of other organizations also are involved in restoration work in the Raritan Region who have collectively implemented over 70 water quality restoration and protection projects. These projects have included dam removal, floodplain property acquisition, reforestation, wetland restoration water gardens, rain barrels, as well as the nonpoint source projects listed previously. Additionally, between 2007 and 2016, the Natural Resources Conservation Service (NRCS) conducted numerous projects that account for over 6,660 (primarily agricultural) BMP practices in the Raritan basin. The NRCS is the primary source of assistance for landowners in the development of resource management pertaining to soil conservation, water quality improvement, wildlife habitat enhancement, and irrigation water management. The USDA Farm Services Agency performs most of the funding assistance.

Identifying and prioritizing future restoration activities

In the effort to optimize resources for restoration efforts, the Department has initiated actions that identify and prioritize future nonpoint restoration efforts at a regional level. The goal of this effort is to maximize the utilization of restoration funding by identifying AUs that show the best potential for improving water quality, identifying areas within the AU that will have the most impact on water quality, and prioritizing these efforts. Initial efforts resulted in the development of WBPs including the seven in the Raritan Water Region that cover 17 AUs. These WBPs have identified management actions needed for nonpoint load reductions in the critical areas of the watershed.

Developing plans to restore and protect the remaining AUs in the region is an immense challenge that requires scientific based planning to identify required nonpoint management actions and prioritizing them. Developing WBPs for all AUs is an arduous task that is not a realistic near-term possibility, therefore, other methods must be developed to identify and prioritize the best candidates for nonpoint restoration efforts.

The Department has initiated identify processes to prioritize AUs for nonpoint restoration by developing a protocol to be used during the regional comprehensive assessment by characterizing water quality data, determining trends, identifying sources and causes, locating restoration efforts, identifying preserved and open space, and verifying nearby water quality impacts. Water quality and biological data are reviewed to identify AUs "on the bubble" which are waterbodies that are close to be fully attaining its water quality criteria by verifying improving determining trends, magnitude and frequency of exceedances of the criteria, habitat conditions. and identifying recent delistings from the 303(d) List. These results along with other nonwater quality data such as restoration projects, land use, impervious surface, preserved open space, point source dischargers, contamination sites, habitat conditions, landfills, stormwater basins, and dams were analyzed to select AUs that showed where nonpoint source projects could

Figure 3.25: Raritan Water Region Restoration Priority Watersheds

in a reasonable time, at a reasonable cost and addressing a reasonable number of sources and causes could achieve water quality improvements at an AU level.

For the Raritan Water Region, 39 AUs were selected encompassing all four watershed management areas where AUs show the best potential in achieving water quality improvements to restore designated uses. A significant number of headwaters and tributaries were selected. These waters were characterized by water quality data near or trending toward the criteria, healthy biological communities nearby, watersheds with a limited number of sources and causes, sufficient undeveloped land use, and intact or limited development in the riparian zones. It is expected that restoration efforts with achievable scopes and funding can make the changes needed in the watershed to restore water quality not only in the headwaters and tributaries but as a collective effort downstream in the larger rivers.

In addition to the comprehensive assessment process, the Department is working on incorporating two EPA tools, the Recovery Potential Screening (RPS) and Watershed Resource Registration (WRR), to improve the selection and prioritization for nonpoint restoration and protection actions. These tools offer flexible, user friendly, technical based, and rapid watershed assessments to identify and prioritize watersheds for restoration and protection. The RPS is an Excel-based tool that provides an approach for comparing watersheds, their conditions and how well they may respond to management efforts. RPS incorporates ecological, stressor, and social indicators to calculate index values at the AU level which can be used to identify watersheds that show the best potential for restoration and protection success. Additional information on RPS is located at the EPA website https://www.epa.gov/rps/overview-recovery-potential-screening-rps. The WRR is an interactive GIS-based tool that also incorporates ecological, social, economic, and stressor data to select and prioritize areas within AUs for protection and restoration. WRR integrates data from regulatory and non-regulatory programs to guide management actions in a transparent, scientific-based method which maximizes watershed benefits and conserves program resources. The

Department is working with EPA in creating the tool for New Jersey and has included other federal, state and local agencies in its development. Additional information on the WRR is located at the website https://watershedresourcesregistry.org/.

Chapter 4: Special State Concerns and Recommendations

4.1 - Chlorides and Total Dissolved Solids

Long term water quality monitoring data show national and state trends of increasing Total Dissolved Solids (TDS) and dissolved chloride concentrations in surface water. Elevated TDS and chloride directly impact aquatic life (including macroinvertebrates, fish and amphibians) and human health, while chloride can also indirectly affect human health by increasing corrosivity and the potential for increased dissolved metals in drinking water.

USGS (Mullaney et al, 2009) ²² conducted a study of chloride in ground water and surface water by analyzing data collected from 1991-2004 in the northern United States. Surface water quality data from 15 of 100 sites, collected primarily in winter, had chloride concentrations higher than the U.S. Environmental Protection Agency (USEPA) recommended aquatic life chronic criterion of 230 mg/L. Upward trends in chloride loads were apparent in several urban basins. Sources of the increased chloride include increases in paved areas and the subsequent road salt usage, increases in wastewater and septic system discharges, recycling of chloride from drinking water, and leachate from landfills and salt storage areas.

In a study of 30 monitoring stations in the northern U.S. by Corsi et al (2015)²³, concentrations of chloride increased substantially over time, with average concentrations approximately doubling from 1990-2011. Long term data showed increasing concentrations in all seasons in most streams, while maximum chloride concentrations occurred during the winter. This suggests that chloride was stored in the soil or shallow ground water system during the winter and gradually discharged in baseflow throughout the year. In addition, increasing chloride trends were observed in watersheds dominated by different land uses, although the magnitude of chloride concentrations, as well as the rate of increase, rose with the amount of impervious land cover in the watershed.

²² Mullaney, J, Lorenz, D. and Arntson, A. 2009. Chloride in groundwater and surface water in areas underlain by the glacial aquifer system, northern United States. U.S. Geological Survey, Scientific Investigations Report 2009–5086. Available at https://pubs.usgs.gov/sir/2009/5086/

²³ Corsi, S., De Cicco, L., Lutz, M., Hirsch, R. 2015. River chloride trends in snow-affected urban watersheds: increasing concentrations outpace urban growth rate and are common among all seasons. Science of The Total Environment Volume 508, 1 March 2015, Pages 488-497. Available at https://doi.org/10.1016/j.scitotenv.2014.12.012

Robinson et al (1996)²⁴ evaluated water quality trends during water years 1975-1986 at 60 stream monitoring stations in New Jersey for statistical association with drainage basin characteristics, including dominant land use, population, wastewater discharges, road salting, fertilizer application, and estimates of soil erosion and irrigated land. Among the correlations observed in the study, it was found that upward trends in specific conductance, sodium and chloride were statistically associated with the amount of road salt applications. In addition, drainage basin size was correlated with upward trends in specific conductance and dissolved chloride, which corresponds with the conservative behavior of chloride in streams that results in larger concentrations in a downstream direction. While wastewater discharges and fertilizer use are also sources of ions, the increased use of road salt during the study period suggests that road salting appears to be a significant source of these dissolved ions.

Hickman and Gray (2010)²⁵ evaluated water quality trends at 70 long-term monitoring sites on New Jersey streams over a ten-year period (1998-2007). Using a statistical method that corrected for flow variation over time, increasing trends in TDS were identified at 24 stations throughout the water regions of the state, while no stations had decreasing TDS trends. When compared to two previous studies that used the same methods, trends of increasing concentrations of TDS were exhibited in 24% of the stations analyzed during water years 1980-1986 (Hay and Campbell, 1990)²⁶, 26% of the stations analyzed during water years 1986-1995 (Hickman and Barringer, 1999)²⁷, and 34% of stations analyzed during water years 1998-2007 (Hickman and Gray, 2010).

In a study by Hickman and Hirsh (2017)²⁸, trend tests were conducted for water years 1980–2011 using two methods to identify trends: Weighted Regressions on Time, Discharge, and Season (WRTDS) models and seasonal rank-sum tests. Results showed upward trends using one or both statistical methods for all 4 stations evaluated for specific conductance, chloride and TDS.

In contrast to the aforementioned studies, Heckathorn and Deetz (2012)²⁹ used a randomly selected probabilistic network of over 370 sites in New Jersey to evaluate statewide trends rather than trends by individual stations. The Heckathorn and Deetz study represents the USGS' most recent analysis

of statewide water quality trends for New Jersey. The report statistically evaluated year-round data from 1998-2009 of TDS as well as January to March concentrations of dissolved chloride, when road salt application is likely to occur. The analysis showed median concentrations of TDS and chlorides increased statewide during the assessment period, while background stations (relatively unaffected by human activity) exhibited no significant variations of median concentrations during the study period.

Sources

TDS and chloride increases have been associated with runoff from urban and agricultural areas, especially runoff of salt used to control ice on roadways, as well as discharges from wastewater treatment facilities and septic systems. Winter storm-related data supports a correlation between road salting and increased TDS and chloride levels in the water column. These growing trends correspond to the rising use of salt for road deicing in the United States, which has increased from about 8 million metric tons in 1975 to 22 million metric tons in 2017^{30, 31}.

A USEPA review of "Environmental Effects from Deicing Compounds" (1973³²) summarized studies that measured chlorides ranging from 1,130 to 25,100 mg/L in highway snowmelt runoff, while studies of stream water quality in winter showed frequent chloride concentrations over 2,000 mg/L.

A 1988 USGS study (Harned, 1988³³) that measured contaminants from highway runoff found that specific conductance and chloride (as well as alkalinity, calcium, sodium, and metals) were greater at the highway stations than in the undeveloped basins. Concentrations of these pollutants was highest during the winter months. It was estimated that highway deicing and sanding supplied 67% of the annual TDS loads from highway runoff.

The "National Management Measures Guidance to Control Nonpoint Source Pollution from Urban Areas" (USEPA, 2005³⁴), identified deicing salts as the primary source of chloride from highway runoff. Studies of snowmelt revealed that chloride, conductivity and TDS increased rapidly in highway runoff because of initial deicing salt applications at each site. Conductivity trends were

strongly correlated with chloride trends. In addition, concentrations of metals in highway snowmelt (lead, copper, cadmium, zinc, and cyanide) were orders of magnitude higher than those measured in the control site.

NJDEP Analysis of TDS and Chloride Trends

Data from the Department's year-round Ambient Surface Water Quality Monitoring Network (ASWQM) show increasing trends in median concentrations of dissolved chloride (Figure 4.1) and TDS (Figure 4.2). There is also evidence that the number of samples which exceed New Jersey's surface water quality standards (SWQS) (N.J.A.C. 7:9B³⁵) for chloride (Figure 4.3) and TDS (Figure 4.4) is increasing. Most of the increases (69% of TDS samples over 500 mg/L and 85% of chloride samples over 230 mg/L) are associated with cold weather months (November through April). This agrees with the results observed in the studies discussed above and corroborates both the measured increasing trends in TDS and chloride and the role of road salt application in these impacts to New Jersey's streams.

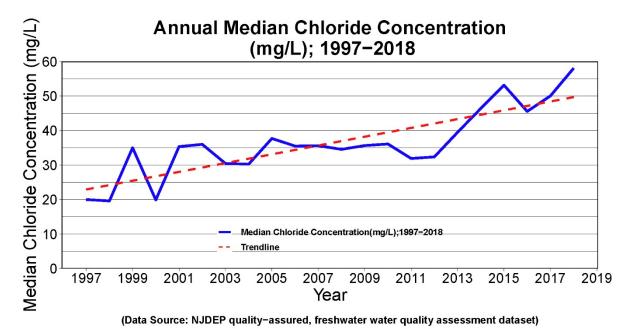

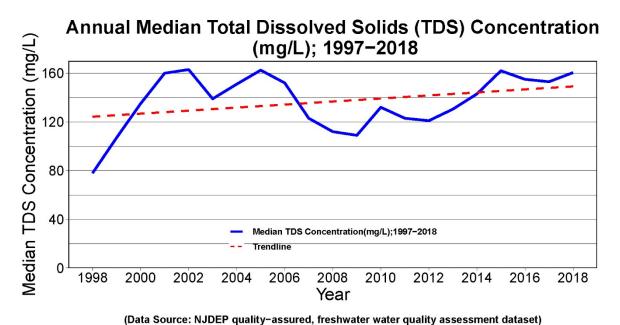

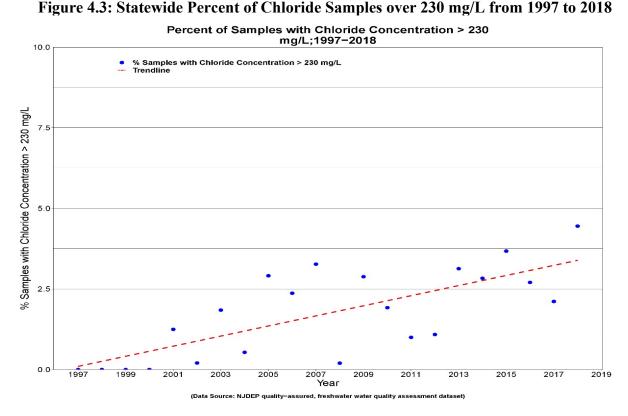

Figure 4.1: Statewide Annual Median Chloride Concentration from 1997 to 2018

³⁵ New Jersey's Surface Water Quality Standards (SWQS) for TDS is 500 mg/L or no adverse effects on the aquatic biota, whichever is more stringent. The SWQS for chloride in fresh waters is 860 mg/L (acute) and 230 mg/L (chronic) for aquatic life and 250 mg/L for human health.

Figure 4.2: Statewide Annual Median Total Dissolved Solids Concentration from 1997 to 2018

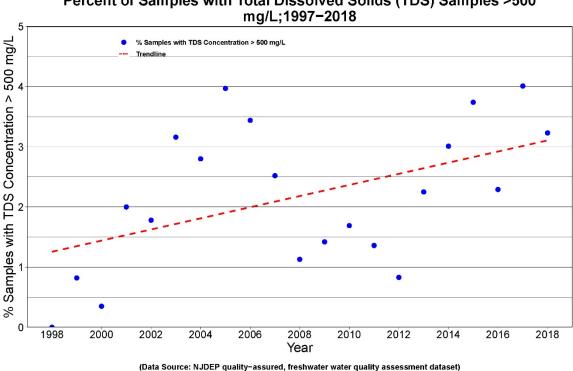

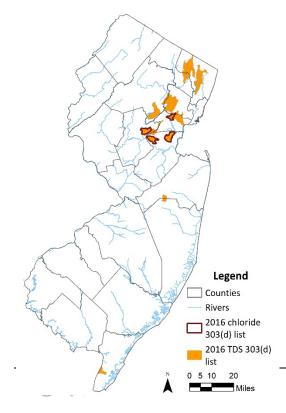

Figure 4.4: Statewide Percent of TDS Samples over 500 mg/L from 1997 to 2018

Percent of Samples with Total Dissolved Solids (TDS) Samples >500

mg/L:1997-2018

Figure 4.5: Assessment Units Impaired for Total Dissolved Solids on the 2016 303(d) List

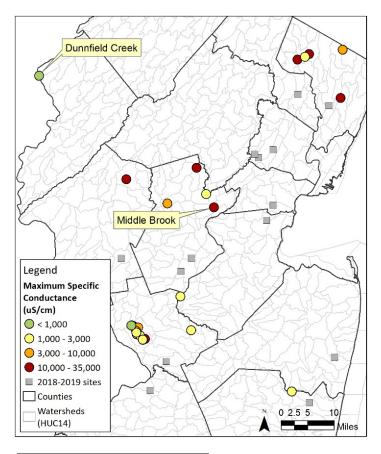

The data reviewed to develop this Integrated Report identified 20 assessment units with use impairments due to exceedances of SWQS for TDS (Figure 4.5) as well as a number of assessment units with high maximum TDS values, but that are not impaired. The number of chloride exceedances remains relatively low and none resulted in use impairments (Figure 4.5). The increasing TDS trends were found in all types of land uses (urban, agricultural, mixed, and undeveloped) and physiographic regions.

NJDEP Continuous Specific Conductivity Monitoring Project

More data is needed to quantify the duration and maximum values of the elevated levels in TDS and chloride and to identify the significance of road salt in the observed trends. Specific conductance (which correlates with the sum of dissolved major ion concentrations in water) is related to TDS and chloride.³⁶ Specific conductance is often used as a surrogate measurement of TDS and chloride because it is easily and accurately measured in the field and supplements laboratory analytical determination of major ions, such as chloride.³⁷

Beginning in 2011, NJDEP (BFBM) deployed continuous specific conductance data loggers in a total of 41 non-tidal freshwater streams with varying levels of urbanization (Figure 4.6). During winter 2011-2012, data were collected at 5 sites, and during winter 2013-2014 data were collected at 7 sites. The project was expanded in 2016-2017 to monitor year-round at 15 sites, which included an intensive study of 11 sites in Shabakunk Creek. Fourteen sites are currently being monitored.

Figure 4.6: Continuous Specific Conductance
Maximum Values

Site-specific continuous specific conductance data were graphed with Continuous weather data. specific conductance data showed substantial increases with significant snowfall events, indicative of when road salt was applied. It's clear that typical discreet sampling cannot identify peak and duration of elevated chloride and TDS concentrations and that these elevated concentrations after winter precipitation events may be much higher than previously thought. 4.7 shows one example of elevated specific conductance levels and how they are associated with precipitation events in winter months.

³⁷ Miller, R. Bradford, W. and Peters, N. 1988. Specific Conductance: Theoretical Considerations and Application to Analytical Quality Control. U.S. Geological Survey Water-Supply Paper 2311. Available at https://pubs.usgs.gov/wsp/2311/report.pdf

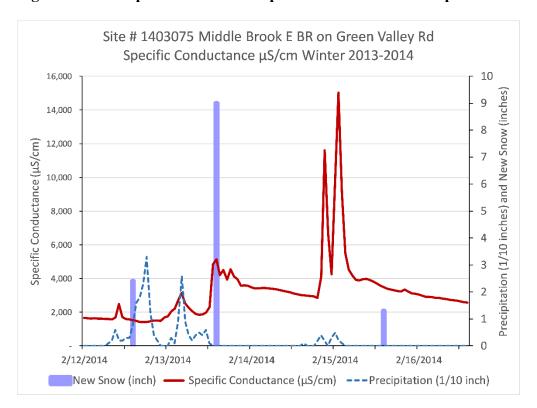

Figure 4.7: Example of Continuous Specific Conductance Compared to Winter Weather

Dunnfield Creek, the reference site for this project, exhibited negligible variability in specific conductance. This assessment unit is 87% forest and only 1% urban (2012 Land Use) with almost no roads. While Dunnfield Creek fluctuated only from 27 to 34 μ S/cm, more urban watersheds varied up to 33,490 μ S/cm. For the 27 sites completed, mean specific conductance ranged from 31 to 4,800 μ S/cm. Medians ranged from 31 to 4,400 μ S/cm. Maximum values varied from 34 to 33,600 μ S/cm.

Management of Road Salt Impacts

The Department has developed required and recommended best management practices as part of its Municipal Stormwater Regulation Program³⁸ to reduce the use and impact of deicing materials. Additional guidance documents are available for highway agencies.^{39,} In addition, the Department has a Snow Removal and Disposal Policy that prohibits the dumping of snow in waterbodies, wetlands, stormwater basins etc. except with an emergency permit from the Department.⁴⁰

³⁸ NJDEP Municipal Stormwater Regulation Program. Available at https://www.nj.gov/dep/dwq/msrp home.htm

³⁹ NJDEP Highway Agency Stormwater Guidance Document. August 2004. Available at https://www.nj.gov/dep/dwq/highway_guidance.htm

NJDEP Emergency Snow Removal and Disposal Policy. December 2014. Available at https://www.state.nj.us/dep/dwq/pdf/snow_removal.pdf

Correlations are being developed between specific conductance and grab samples analyzed for TDS and chloride and with land use and road characteristics. Road salt usage and loading trends are being compiled and other states' approaches to reduce road salt impacts are under review, including TMDLs and BMPs. These efforts will inform the Department's technical and implementation approach to address the increasing trends in TDS and chloride concentrations and surface water impairments.

4.2 - Cyanobacteria

Cyanobacteria are a type of bacteria capable of photosynthesis. Although they are not true algae, they are often referred to as "blue-green algae". Cyanobacteria frequently impart off-tastes and odors to the water in which they grow, and sometimes they produce toxins that can be harmful to the health of humans and other animals. Although problems related to cyanobacteria most often occur in freshwaters (lakes and streams), cyanobacteria can also be found in marine waters.

A cyanobacterial Harmful Algal Bloom (HAB) is the name given to the excessive growth or

"bloom" of cyanobacteria some of which can produce one or more types of potentially harmful toxins. HABs can occur under suitable environmental conditions of light, temperature, nutrients, and calm water. These "blooms" often result in a thick coating or "mat" on the surface of a waterbody, often in late-summer or early fall. A HAB can be dangerous to people, animals or the entire ecosystem. Some, but not all, HABs produce chemicals that can be toxic to humans and animals if ingested, inhaled, or if contacted by skin or mucous membranes. Low concentrations of cyanobacteria cells regardless of toxin production may cause allergenic and/or irritative effects.

There is limited information whether these toxins can accumulate in fish and shellfish. However, it is cautioned to not consume fish or shellfish when a HAB is present.

The Department has developed the capacity to perform enhanced monitoring and analysis of these toxins as well as response strategies for advisories and actions in both freshwater and marine water. For freshwater, the Department recently published the "New Jersey Cyanobacterial Harmful Algal Strategy", Bloom (HAB) Response https://www.state.nj.us/dep/wms/bfbm/download/NJHABResponseStrategy.pdf, that provides a statewide approach to responding to cyanobacterial HABs in freshwater recreational waters and sources of drinking water. The Response Strategy is designed to identify: entities responsible for response and actions; recreational risk thresholds; acceptable parameters and methods for assessing risk; appropriate monitoring and analysis for toxins; and recommended advisories and other appropriate communication mechanisms. The scope of the Response Strategy is for lakes, rivers, and streams with potential public access, recreational use, bathing beaches, and sources of drinking water. In 2018, the Department received 32 reports of HAB freshwater events located mostly in northern and central areas of the state. Of these incidents, 63% were confirmed to have cyanobacteria present, while 37% confirmed no cyanobacteria. Where HABs were confirmed, advisories were posted at recreational areas, bathing beaches closed, and/or drinking water purveyors were notified per Strategy guidelines.

Direct drinking water concerns are addressed in the Department's Division of Water Supply and Geoscience (DWSG) Emergency Response Plan, which focuses on prevention and treatment of drinking water contamination and is applicable to cyanobacterial HABs and toxins. In addition, DWSG is working with utilities to develop management plans based on the 2015 USEPA "Recommendations for Public Water Systems to Manage Cyanotoxins in Drinking Water."

In marine waters, the Department's Algal Bloom Monitoring Program has been conducting phytoplankton monitoring to ensure safe shellfish harvesting. There are two components to the monitoring program including phytoplankton monitoring at fixed station and aircraft remote sensing for chlorophyll during the summer. The fixed monitoring network gives a representative overview of the estuarine waters of New Jersey and are sampled year-round for HABs. The aircraft remote sensing identifies algal blooms in coastal waters and samples are then taken to determine if cyanobacteria are present. As part of the State's compliance with the National Shellfish Sanitation Program (NSSP), the Department is required to develop a Biotoxin Contingency Plan that includes control measures for marine biotoxins.

Additional information on Harmful Algal Blooms can be found on Department websites: Freshwater Harmful Algal Blooms website: https://www.state.nj.us/dep/wms/HABS.html Marine Water Algal Bloom website: https://www.state.nj.us/dep/wms/bmw/phytoplankton.htm

4.3 - Vibrio parahaemolyticus (Vibrio)

Vibrio parahaemolyticus or "Vibrio" is a naturally occurring⁴¹ bacterial pathogen found primarily in coastal (saline) waters. Eating shellfish contaminated with Vibrio may cause illnesses ranging from gastrointestinal problems to death (in immunocompromised individuals). Exposure may also cause wound infections; however, the primary human health concern is shellfish consumption.

Prior to 2002, there were no reported illnesses caused by Vibrio in New Jersey; however, they were reported in other parts of the country. On two occasions between 2002 and 2005, New Jersey closed roughly 100-square miles of the Delaware Bay to shellfish harvest due to the presence of Vibrio in shellfish. The Department confirmed reports of two illnesses in 2014 caused by *Vibrio parahaemolyticus (Vp)* that were attributed to Delaware Bay oysters; one was harvested from Shell

⁴¹ Naturally-occurring means that this pathogen is not related to human waste or pollution. It is an organism that is normally present in bay waters in low numbers. Under ideal conditions (primarily warm temperatures), this organism thrives both in the water and in the shellfish tissue after harvest of the shellfish.

Rock oyster beds and one from Cohansey oyster beds within New Jersey waters. These sporadic illnesses did not result in an outbreak or closure.

The Department samples oysters harvested from New Jersey waters on an annual basis and tests for the presence of Vibrio. Water analyses have also been performed but showed no correlation between Vibrio in the water column and Vibrio in oyster tissue samples. Closures are put into place when a pathogen outbreak is declared, based on the requirements of the National Shellfish Sanitation Program guidelines. Shellfish beds are reopened if additional oyster sampling from the implicated area shows no presence Vibrio, the conditions that existed at the time attributed to the illnesses no longer exist (e.g. air temps, water temps), or when the season for Vibrio outbreaks is over (August 31st).

It is important to emphasize that this pathogen is not related to pollution. It is normally present in low numbers in coastal waters throughout the country. Under certain conditions, the pathogen thrives and increases its presence in the oysters. Factors that favor the pathogen's growth are not fully understood; however, ongoing research by the Department (2011-2015), has shown that elevated temperature (in the oyster after it is harvested) can play a significant role. This research also shows that immediately cooling the product or decreasing the time to refrigeration after harvest can control the level of *Vibrio parahaemolyticus (Vp)* in oysters. The Department's research shows that the highest level of *Vibrio parahaemolyticus (Vp)* occurs during the month of June, and that the majority of reported occur in late June and early July for New Jersey. The Department annually implements a *Vibrio parahaemolyticus* Management Plan, which is effective from June 1st to August 31st. This plan regulates the time from harvest to refrigeration, has tarping requirements to reduce heat impact from the sun on oysters, and allows for unlimited harvest hours for vessels with onboard refrigeration. The Plan based on these studies, appears to be working.

4.4 - Emerging Contaminants

PFOA/PFOS

Perfluorooctanoic acid (PFOA) and perfluorooctanesulfonic acid (PFOS) are part of a larger group of chemicals called per- and polyfluoroalkyl substances (PFAS) that have been widely produced and used industrially and commercially. Both PFOA and PFOS may be found in consumer products, such as stain resistant coatings for upholstery and carpets, water resistant outdoor clothing and grease-proof food packaging. PFOA may be used in the manufacture of non-stick cookware, and PFOS is used in Aqueous Film Forming Foam (AFFF, used for fighting petroleum-based fires), metal plating and finishing. Although the production of PFOA and PFOS has ceased in the United States, these substances are still sometimes used by secondary industries, including the manufacture of heat resistant and water-resistant fabrics. Contamination from PFOA and PFOS is expected to continue indefinitely due to their extreme persistence in the environment, the fact that they are soluble and mobile in water and their continued production in other nations.

PFOA and PFOS have been detected across various environmental media and in drinking water supplies, and they pose serious threats to wildlife and humans. Studies have found PFOA and PFOS in the blood serum of the general population, and it is estimated that most people in the United

States have been exposed to one or more PFAS, with PFOA and PFOS being the most common 42. PFOA and PFOS bioaccumulate and can cause adverse health effects at low levels since they persist in the body for many years. They are developmental toxicants, liver toxicants and immune system toxicants; the EPA has also found suggestive evidence that they may cause cancer 43. PFOS has been shown to accumulate to levels of concern in fish, and some states have issued fish consumption advisories for certain water bodies 44. New Jersey's fish consumption advisories are available on the Department's website, https://www.nj.gov/dep/dsr/publications/Investigation%20of%20Levels%20of%20Perfluorinated%20Compounds%20in%20New%20Jersey%20Fish,%20Surface%20Water,%20and%20Sediment.pdf

In 2006, the Department initiated a study to evaluate the occurrence of PFOA and PFOS in surface and ground water sources and treated water of public water systems located in areas downstream of expected contamination sources. PFOA was detected at 78% of the systems sampled, and PFOS was detected at 57% of the systems sampled (report available https://www.nj.gov/dep/dsr/dw/final pfoa report.pdf). A follow-up occurrence study in 2009 was conducted statewide where PFOA was detected in 55% of the 33 systems sampled and PFOS in 27% (report available at https://www.nj.gov/dep/watersupply/pdf/pfc-study.pdf). In 2014, the Department requested that the New Jersey Drinking Water Quality Institute (DWQI) develop recommendations for drinking water Maximum Contaminant Levels (MCLs) for PFOA, PFOS and another PFAS, perfluorononanoic acid (PFNA). An MCL and a groundwater quality standard for PFNA of 13 ng/l (0.013 µg/l) was adopted in 2018. EPA issued a Drinking Water Health Advisory in 2016 for PFOA and PFOS at 70 ng/L individually or a total of the two compounds when both compounds are found. However, the DWQI did not find EPA's advisories to be sufficiently protective and recommended an MCL for PFOA of 14 ng/l in 2017 and an MCL for PFOS of 13 ng/l in 2018. The Department proposed MCLs and ground water quality standards for both PFOA and PFOS based on the recommendations of the DWQI in April 2019 with an expected adoption in 2020.

Microplastics

Plastic particles smaller than 5 mm in size are called microplastics, and they have been documented in marine and freshwaters worldwide. There are two types of microplastics: plastics manufactured to a small size (primary) and fragments of larger plastic pieces (secondary). It is estimated that 8

trillion primary microplastics enter aquatic habitats in the United States daily; however, secondary microplastics and microfibers, which result from the shedding of synthetic fibers from clothing or textiles, are thought to be far more abundant⁴⁵. Plastics do not biodegrade but rather break down into continually smaller pieces via photodegradation and mechanical abrasion. Although microplastics have been more thoroughly documented in the marine environment, freshwater systems have been shown to have concentrations equal to or greater than marine systems. Major sources of microplastics in aquatic habitats include discharges from wastewater treatment plants, atmospheric deposition, improperly disposed trash, and non-point sources such as combined sewer overflows (CSOs) and runoff.

Microplastics have chemical and physical properties that make them potentially hazardous to aquatic life and human health. They are ingested by a variety of organisms due to their prevalence and substantial variation in size and appearance. Microplastics have been shown to move through natural food webs and have been found in species across trophic levels, including those consumed by humans, such as finfish and shellfish⁴⁶. The chemical composition of plastics includes monomers, such as bisphenol A, styrene and vinyl chloride, and additives, such as plasticizers (phthalates), antimicrobials (triclosan) and flame retardants. These monomers and additives can potentially leach out of plastic as it degrades. Due to their high surface area to volume ratio, microplastics can also adsorb and concentrate environmental contaminants including persistent organic pollutants (POPs) and other hydrophobic chemicals, heavy metals, and pathogens⁴⁷.

Microplastics are widespread in New Jersey waters. Ravit et al observed microplastics in all sampled locations in the Raritan and Passaic River watersheds and demonstrated that POPs are associated with plastic particles⁴⁸. Estahbanati and Fahrenfeld found microplastics in all size categories in all samples collected upstream and downstream of four major municipal wastewater treatment plants along the north and south branches of the Raritan River⁴⁹. NY/NJ Baykeeper collected samples in the NY-NJ Harbor Estuary in 2015 and found an average abundance of 256,322 plastic particles per square kilometer⁵⁰. New Jersey is the most densely populated state, and population density likely contributes to microplastic abundance.

In March 2015, New Jersey became the second state to ban "non-biodegradable" microbeads from personal care products. Later that year, the federal Microbead-Free Waters Act passed, prohibiting the manufacture and use of microbeads in personal care products by 2018. The Department tasked the Public Health Standing Committee of the NJDEP Science Advisory Board (SAB) with investigating the potential human health impacts of microplastics and nanoplastics (diameter < 0.1 **Findings** and recommendations from this report are available https://www.state.nj.us/dep/sab/NJDEP-SAB-PHSC-final-2016.pdf. The SAB noted a lack of human health data and recommended that the Department continue to monitor future research as it becomes available for information on the presence of microplastics in New Jersey environmental media and biota and evidence of human exposure and health effects.

4.5 - Impacts of Climate Change on Water Quality

The National Oceanic and Atmospheric Administration's 2017 State of the Climate report, led by scientists from NOAA's National Centers for Environmental Information and published by the Bulletin of the American Meteorological Society, made several notable findings; levels of greenhouse gases were the highest on record, the rate of sea level increase is higher than before, heat in the upper ocean hit a record high, and global land and ocean combined surface temperature reached a near-record high. In addition, sea surface temperatures hit a near-record high, arctic and Antarctic sea ice coverage fell to a record low, and unprecedented multi-year coral reef bleaching continued. More than 500 scientists from 65 countries contributed to the report, which found that the 10 warmest years on record have occurred since 1998 (see NOAA's Web site at https://www.climate.gov/news-features/understanding-climate/state-climate-highlights/2017). In 2019, NOAA published the New Jersey State Climate Summary, which provided the following key messages:

- Heat waves are projected to be more intense while cold waves are projected to be less intense
- Winter and spring precipitation and extreme precipitation events are projected to increase in the future
- Global sea level is projected to rise one to four feet by 2100. Sea level rise poses substantial risks, including greater vulnerability to severe coastal flooding.

USEPA has stated that, "Temperature change drives other changes in natural environmental processes that in turn affect the quality and quantity of our water resources". The table below lists the potential impacts (warmer waters, increases in tropical storm intensity, sea level rise, precipitation changes, and ocean and coastal changes) identified by the USEPA, along with their anticipated effects on water resources⁵¹:

Page | 84

⁵¹ Metchis, Karen, USEPA Climate Change Advisor. *Climate Change and the EPA National Water Program*, USEPA Office of Water, Powerpoint presentation, May 11, 2010. Available at www.epa.gov/ow/climatechange/strategy. Viewed on June 20, 2010.

Table 4.1: Climate Change Impacts on U.S. Waters

| Potential Impact | Anticipated Effect on Water Resources | |
|----------------------------------|--|--|
| Changes in Temperature: | Changes in the distribution and survival of aquatic species, algal blooms, and lower dissolved oxygen levels. | |
| Changes in Precipitation: | Reduced groundwater and surface water supply in some areas Reduced reliability of snow pack to replenish reservoirs and aquifers Droughts Wildfires Increased water demand due to higher temperatures Increased runoff resulting in erosion and sedimentation Overwhelmed water infrastructure due to flooding | |
| Increases in Storm Intensity: | Contaminated Waters Damaged Wetlands Flooded Wastewater Treatment Plants | |
| Sea Level Rise: | High Wind Damage Displacement of coastal wetlands and habitat Increased coastal erosion Salt water intrusion in drinking water supplies Inundation of wastewater treatment infrastructure | |
| Ocean and Coastal Changes: | Biological habitat changes as the air temperatures increase Estuarine waters become more saline as sea levels rise Ocean temperatures increase Ocean acidification | |

All of these expected conditions would have a significant impact on New Jersey's waters. In its strategy, USEPA urged states to "assess emerging climate change information, evaluate potential impacts of climate change on water programs, and identify needed responses."

Vital Signs of New Jersey Climate

Anthropogenic warming due to the emission of greenhouse gases has contributed to a global rise in temperature of about 1 degree Celsius since 1880⁵². We know this because if the warming were caused by cyclical factors, such as solar irradiance, we would expect to see warmer temperatures in all layers of the atmosphere. Instead, they have observed a cooling in the upper atmosphere, and a warming at the surface and in the lower parts of the atmosphere. That's because greenhouse gases are trapping heat in the lower atmosphere. New Jersey's climate has warmed by about 1.7 degrees C in the last century⁵³. In that time, sea level rose by 12-16 inches, very likely the fastest rate the

⁵² Global surface temperature | NASA Global Climate Change. Climate Change: Vital Signs of the Planet. 2018 [accessed 2018]. Available at https://climate.nasa.gov/vital-signs/global-temperature/

⁵³ Environmental Protection Agency. What Climate Change Means for New Jersey. 2016.

New Jersey shore has seen in the last 4,000 years⁵⁴. The additional projected sea level rise of up to 3 feet by 2100 will only further increase the number of people at risk from large storm events like Hurricane Sandy. In fact, a sea-level rise of 1.5 feet would cause a 1 in 10-year flood at Atlantic City to exceed the highest flood level experienced over the last century⁴. Impacts from sea level rise include saltwater intrusion and contamination from flooding due to erosion and contaminants from runoff or failure of low-lying treatment infrastructure. In addition, damage from storm surge during extreme weather events will be heightened.

In 2007, New Jersey established its leadership role in the efforts to address global climate with the passage of the Global Warming Response Act. This law requires stabilization of statewide greenhouse gas emissions to 1990 levels by 2020, followed by a further reduction to 80 percent below 2006 levels by 2050. Meeting the requirements of the Global Warming Response Act and determining how best to adapt to those climate-related impacts throughout New Jersey that are unavoidable will involve the combined efforts of many other programs within the Department, as well as those in other state agencies.

In December 2009, the Department released Meeting New Jersey's 2020 Greenhouse Gas Limit: New Jersey's Global Warming Response Act Recommendations Report, as required by the Global Warming Response Act. This report provides analyses of significant sources of greenhouse gas emissions; details a broad range of options and outlines mitigation strategies for meeting New Jersey's statewide 2020 greenhouse gas limit; and provides a framework for how the State needs to move forward to meet its statewide 2050 greenhouse gas limit. The report is available for download from the Department's Web site at http://www.nj.gov/dep/oce/gwr.htm. The report addresses all major sources of greenhouse gas emissions in New Jersey, including transportation, electricity generation, industry, residential buildings, and the commercial sector. The report also addresses sectors such as forestry and agriculture that naturally help reduce greenhouse gas emissions by sequestering carbon dioxide. As such, the report provides a comprehensive technical and financial framework for decision-making related to various greenhouse gas reduction strategies. As part of that report, the State highlighted the critical need for adaptation planning and action, and recommended undertaking a comprehensive adaptation planning process. In response, the Department expects to develop a comprehensive adaptation plan to help New Jersey citizens handle the unavoidable impacts of climate change.

On February 21, 2018, Governor Murphy signed <u>P.L. 2018</u>, c.3, requiring New Jersey to join the US Climate Alliance, a bipartisan coalition of US states committed to uphold the <u>United Nations' Paris Climate Accord</u> despite the federal government's decision to withdrawal. On the one-year anniversary of the US's withdrawal, the Climate Alliance committed to several new actions, including cuts in short-lived climate pollutants such as methane and black carbon, and financing for clean energy.

Page | 86

⁵⁴ Miller K, Kopp R, Browning J, Horton B. *Sea-Level Rise In New Jersey Fact Sheet*. Rutgers Department of Earth and Planetary Sciences and Institute of Marine and Coastal Sciences; 2014. Available at https://geology.rutgers.edu/images/stories/faculty/miller-kenneth-g/Sealevelfactsheet7112014update.pdf.

The Department is also coordinating several important adaptation-related actions including the following:

- A study led by the City University of New York (CUNY), in collaboration with team members from Rutgers and Columbia Universities, to estimate the economic consequences (costs and benefits) of climate change for ten sectors of New Jersey's economy during the 21st century, with a primary focus on the 2020 and 2050.
- The Department's Office of Coastal Planning developed the Coastal Community Vulnerability Assessment Protocol (CCVAP) to improve the hazard resilience of coastal communities. CCVAP is a GIS-based methodology intended to assist land use planners, hazard mitigation planners, and emergency managers in the identification of their community's social, infrastructure, and environmental vulnerabilities to coastal hazards and inundation. The protocol relies upon the development a coastal vulnerability index to identify hazard prone lands, incorporating six variables into a composite overlay analysis, including geomorphology, slope, flood prone areas, storm surge inundation, soil drainage, and erosion. The coastal vulnerability index also allows for the incorporation of sea level rise scenarios (.5, 1.0, and 1.5 meter) and their impacts on present storm surge models which can assist communities in identifying their vulnerabilities to the potential effects of climate change. By using the coastal vulnerability index, New Jersey coastal communities can then use their knowledge of present and future hazard scenarios to identify vulnerable populations, capital investments, and natural resources.
- The Bureau of Climate Resilience Planning (BCRP) is also a participant in the Mid-Atlantic Regional Council on the Ocean's (MARCO) workgroup. In 2016, MARCO released a report on the role of Mid-Atlantic coastal wetlands in reducing climate risk. The report examines current practices for identifying and prioritizing wetlands for their ability to reduce climate risk and enhance climate resilience in the region. The report, prepared by the Environmental Law Institute (ELI), identifies opportunities for improving how coastal wetlands can serve as climate buffers in the coastal states of New York, New Jersey, Delaware, Maryland and Virginia.
- The Department's Division of Fish of Wildlife, Office of Natural Lands Management, and Office of Climate and Energy are participating on a multi-stakeholder workgroup that also included the New Jersey Conserve Wildlife Foundation, Conservation Resources, Inc., Nature Conservancy, New Jersey Audubon Society; and American Littoral Society. The workgroup is developing a comprehensive wildlife adaptation plan as part of the State Wildlife Action Plan initiative.
 - a. Update: In 2017, the Division of Fish and Wildlife issued a complete revision of the initial Wildlife Action Plan. The plan is an assessment of the health of the state's wildlife and habitats, the problems they face, and actions that are needed to conserve them over the long term.
- The Department has convened several internal adaptation workgroups to coordinate and collaborate on various ongoing New Jersey adaptation efforts, including a water adaptation

workgroup that is currently identifying the tools needed to address water-related impacts from climate change (e.g., new planning and modeling tools).

- The Department is participating on a Northeastern States for Coordinated Air Use Management (NESCAUM) Adaptation Workgroup designed to coordinate and collaborate on regionwide adaptation issues (e.g., data collection and storage, shared frameworks, and communications)
- The Department is participating, through the Partnership for the Delaware Estuary, in the National Oceanic and Atmospheric Administration (NOAA) Climate-Ready Estuaries Program.

In 2019, the DEP announced its first Chief Resilience Officer and created the Climate & Flood Resilience Program. This program will serve as a "hub" responsible for coordinating the climate change resilience and adaptation work ongoing in many programs across the DEP. The Division of Energy, Security and Sustainability (DESS) reports to Air Quality, Energy and Sustainability (formerly Climate and Environmental Management), to coordinate the various programs involved in mitigating and/or adapting to climate change. DESS in coordination with key water programs within the Department, developed the following list of priorities for Waters of New Jersey, for discussion at the June 2010 National Climate and Water Conference:

Pressing Issues of Concern

- 1. Continue coordination of ongoing efforts (federal, regional, state and local; government and non-government), including:
 - Climate-ready Estuaries Program.
 - USEPA National Water Program Strategy: Response to Climate Change
 - U.S. Climate Change Science Program/Adaptation Taskforce Water Resources Workgroup.
 - How to Consider Climate Change in Coastal Conservation (NOAA)
 - NRCS flooding impacts on infrastructure.
- 2. Need for a suite of models/inputs (e.g., agreed emissions scenarios) that states can use for planning purposes (e.g., water supply planning):
 - Downscaling/regionalization/localization of climate-related models for sea level rise, precipitation, and temperature projections, and impacts on water quality and quantity.
 - Regionalized inputs/parameters for precipitation, sea level rise and temperature, and impacts on water quality and quantity.
 - Guidance on how best to use models and other tools for planning purposes.
- 3. Development of regional indicators:
 - Ensure that requests from USEPA to states for data and methodologies are achievable given states' resource constraints.
- 4. Need for feedback mechanism:
 - New information, lessons learned, and modified priorities need to be incorporated into ongoing water adaptation processes to help provide clear guidance for decision-making.

- Recommendations on how to evaluate the success of adaptation and resilience building efforts.
- 5. Required coordination and collaboration of federal agencies:
 - Ensure compatibility of databases (e.g., USEPA and USGS database retrievals are now compatible, but NOAA's is not (as it is proprietary)).
 - Ensure inclusion of all relevant agencies (e.g., USEPA, USGS, NOAA Climate Service, U.S. Department of Interior, U.S. Fish and Wildlife Service, and U.S. Department of Agriculture).
 - Develop a consistent framework for coordination/collaboration of federal agencies.
 - Designate a lead agency for each issue that states/locals can coordinate through.
 - Engage local stakeholders, including states and local governments, throughout the planning and implementation phases.

Data Gaps (not only identifies areas where additional observational data is needed, but identifies areas where federal analysis of the data is needed):

- Shifts/migration in species: need more data/systematic research to generate scientific conclusions; anecdotal data indicates species shifts.
- Sediment transport and budget for wetlands: needed to support wetlands mitigation and flood retention functions.
- Ocean acidification: need a study similar to NOAA's for the NY/NJ Harbor and the Delaware Bay.
- Baseline shoreline data from overflights with extensive ground truthing to provide latitude/longitude (LIDAR provides elevation).
- Extensive ground truthing of latitude/longitude/elevation data.
- Coordinated assessment of sea level rise's cumulative impacts related to stormwater, tides, and increasing storm surges.
- Connecting climate research with water resources research (e.g., the Department and Rutgers University are discussing development of a computer model to assess the impacts of land use and climate changes on the yield of the Boonton Reservoir System). USEPA climate and water research should focus on similar projects to address other pressing issues in a variety of hydrologic settings addressing water quality and quantity impacts.

Ongoing and Completed Research Related to Water Resources:

- Rutgers University and City University of New York (CUNY) study to investigate vulnerabilities to climate extremes and climate change in coastal New Jersey before and after Hurricane Sandy (published 2014)
- Northeast States of Coordinated Air Use Management's indicators study: focused on precipitation and SLR inputs through the Northeast.
- Mid-Atlantic Regional Council on the Oceans (MARCO) regional initiative: focus is on water quality, habitat protection, climate change adaptation, and offshore renewable energy.
- New Jersey Geological Survey salt water intrusion monitoring in Cape May, Raritan Bay & Lower Delaware River.

- Collaborative Research: Climate Change and Responses in a Coupled Marine System. National Science Foundation. Rutgers University; U. Massachusetts Amherst, Virginia Institute of Marine Science, and Old Dominion University. Project investigates the complex and changing ocean systems, given evidence of cumulative problems related to overfishing, climate change, and other stressors and recognition of limitations in current modes of governance. Of specific interest are the effects of climate change on the fishery and how those effects are perceived, interpreted, and responded to by scientists and by public and private sector actors, which influences the nature of feedback in the coupled system.
- USEPA Region 2 RARE grant "The Role of Eutrophication in Coastal Wetland Fragmentation, Barnegat Bay, New Jersey"
- This past fall (2018) 15 organization banded together to form the New Jersey Tidal Wetlands Monitoring Network. These groups are conducting long term monitoring on the health and resilience of NJ tidal wetlands.
- NJDEP is working with Penn State University to add NJ tidal wetland monitoring and assessment data to the Reference Wetland Database.

• The Partnership for the Delaware Estuary is developing The Site-Specific Salt Marsh Decision Support Tool. The tool integrates data regarding a suite of attributes shown to be essential for proper salt marsh function in order to help practitioners systematically discern the handicaps of specific locations (e.g. elevation deficiencies, limited sediment supply, excessive wave erosion).

In December 2009, the New Jersey Clean Water Council (NJCWC) sponsored an informational session and public hearing on Water Policy and Climate Change. The purpose of the hearing was to seek public testimony on the risks posed to water quality and water infrastructure by climate change and on effective means to manage those risks. Specifically, the NJCWC wanted to know: "What are the high priority risks to clean water posed by the increasing variability of climate and weather events?" and "What changes to water management policies are needed to increase flexibility and adaptive management, and how will New Jersey meet the cost?" Specific recommendations were sought on the following issues: stormwater, wastewater, drinking water, instream/passing flows, agriculture and green industry, and water infrastructure. The NJCWC heard or received written testimony from agency representatives, scientists, utility managers, environmental advocates, and planners.

There was general consensus that climate change is occurring, and it is affecting water resources in a variety of ways, including warmer air and surface water temperatures, more intense storms intermixed with longer periods of dry weather, and rising sea levels. While the contributory causes may be debated, the potential impacts of climate change on water resources and related infrastructure need to be clearly identified and properly managed. New Jersey's weather is already showing a pattern of increased flooding and drought - with both events frequently occurring in the same year. Likewise, sea levels are rising in this coastal state at a rate that exceeds other U.S. coastal areas. All of these effects could have implications for water quality. As important decisions regarding the state's infrastructure are being made, these facts need to be recognized and considered.

New Jersey has largely been focusing efforts on reducing greenhouse gas emissions (otherwise known as mitigation strategies). Since climate change is a world-wide process that is already modifying New Jersey resources, proactively adjusting our resource management strategies is also a rational and necessary response. The over-arching message from the public hearing and supported by the NJCWC is that New Jersey should integrate consideration of the effects of changing climatic conditions into its planning, assessment, and regulatory programs to increase program flexibility, avoid or adapt to foreseeable negative impacts, and maximize programmatic and fiscal efficiency. The following summarizes the results of the public hearing:

What Are The High-Priority Risks To Clean Water Posed By The Increasing Variability Of Climate And Weather Events?

• Baselines are changing: It is no longer acceptable to design for the future based on past records, e.g., "100-year storm frequency" and 7Q10 flow statistics may no longer be accurate for planning and regulating. Accurate measurements and predictions of sea level are necessary for infrastructure repair/replacement. Accurate flood evaluations and predictions are necessary to protect public safety. Additional monitoring may also be necessary.

- Infrastructure may be at risk from multiple effects: Coupled with a repeat of the 1960s drought-of record, increases in sea level rise & tidal excursions up river could put some (Delaware River) surface water intakes at risk. As such, the vulnerability of wells and well fields need to be assessed. Since water infrastructure usually links to waterways or coasts, the secure and protected location of infrastructure (pipelines, intakes and discharges), as well as new development, is critical.
- Water quality effects are largely unknown; synergistic effects may be heightened: For example, higher temperatures that encourage bacterial growth could also result in higher levels of arsenic and other metals in water as they are made available through biological processes. In addition, dissolved oxygen levels could fall, imperiling sensitive aquatic species.
- Climate change could exacerbate existing problems: Impacts associated with development, population growth, and aging infrastructure are likely to be exacerbated by climate change effects on energy and water demand.
- New Jersey is vulnerable to sea level rise: It is undisputed that sea levels are rising. Although the projected rate of future change is subject to debate, a vulnerability analysis needs to be conducted and steps taken now to begin mitigating problem areas. Expected impacts include:
 - Further upstream advances of saline water affecting water intakes; salt water intrusion into aquifers
 - More homes and industries vulnerable to coastal flooding may prompt revisions to programs that support rebuilding in damaged coastal and other flood prone areas
 - Wetland protection and restoration programs could be jeopardized by inundation
 - Changes to natural systems (wetlands and shorelines)
 - Infrastructure disruption pipelines, treatment works, etc. in coastal and low-lying riverine areas
- **Increase in storm intensity:** Whether this is a short or long term effect remains subject to debate. However, water management policies need to consider the potential impacts of changes in the delivery of precipitation (snow and rain) on existing and proposed development and the use and provision of water including:
 - Longer drought periods affecting water supply plans, pricing & conservation
 - Wetland ecosystem changes
 - Increasing incidence of wildfires during extended dry periods (especially in the Pinelands)
 - Overloaded wastewater treatment plants during heavy rain events
 - Lower lake levels and degraded water quality affecting recreation and tourism
 - Soil moisture impacts affecting agriculture from both drought and flooding
 - Annual streamflow changes could affect mixing zone allocations and permit limits
 - More urban flooding affecting water quality, stormwater management design and cost
 - Seasonal variations in the availability of drinking water (especially southern NJ)
- Local and regional temperatures have been rising and the earth is getting warmer: Impacts could affect stream classifications, uses, and discharge controls. Warmer air and water

could be responsible for localized aquatic organism changes, algal blooms, and lower dissolved oxygen (DO) levels. Attention needs to be given to such issues as:

- Greater evapotranspiration, which reduces recharge and stream flows
- Increased water demand, stressing existing supplies
- Warmer water shifting aquatic species distribution and population
- Increased range of invasive aquatic plants
- Fish spawning, seasonal migration, and survival
- Lower DO, more algal blooms and larger hypoxic zones
- Coldwater fisheries*
- Endangered species (e.g., Dwarf Wedgemussel)*
- Terrestrial/aquatic interactions*
- Potential Increase in Waterborne Pathogens*

What Changes To Water Management Policies Are Needed To Increase Flexibility And Adaptive Management, And How Will New Jersey Meet The Cost?

- **Programmatic flexibility:** The State needs to be able to respond effectively and efficiently so that the application of programs and policies remain relevant as conditions change. The Department may need improved monitoring, analysis and feedback pathways to ensure this flexibility. The goal is to ensure that policies, prioritizations, and resources are adjusted to meet desired outcomes. For example, how/should we adapt the regulatory framework to climatecaused water quality changes? Are climate-caused water quality changes considered "natural conditions"? How do climate-caused water quality changes affect the regulation of dischargers? What are the impacts on regulatory policies for drinking water, wastewater, antidegradation, anti-backsliding, and TMDLs?⁵⁶
- Adaptive management: The Department's report entitled, "Meeting New Jersey's 2020 Greenhouse Gas Limit: New Jersey's Global Warming Response Act Recommendations Report"(NJDEP 2009), offers direction that can be applied to adaptive water resources management. The NJCWC is available to work with Department staff to evaluate and develop additional strategies.

- A holistic approach: All three components of water management supply, distribution, and treatment must be considered holistically. Smart growth planning concepts can be considered in concert with water management policies to ensure effective implementation.
- Finance through existing funds and programs: Financing new initiatives is especially problematic in the current fiscal climate, making the leveraging of staff and financial resources necessary. Cost savings should not lead to inaction, because action is necessary now. Changing existing programs to incorporate consideration of potential climate change effects would be one cost-effective way to encourage adaptive management.
- Efficiency: Testimony supported efficiencies in energy use, water use and reuse, land use and redevelopment. Many existing programs, policies, and practices could be given more emphasis to achieve financial and resource efficiencies, including, but not limited to LEED certification programs and green building codes, green infrastructure for stormwater management, the policies of the State Development and Redevelopment Plan, and energy efficiency programs for property owners. Efficiency in permitting and improved communication and coordination were cited as desired strategies, which should be employed both within the Department and between the Department and other agencies. For example, agricultural water management should be more closely linked with the Department's water management programs. Efficient irrigation techniques, drought tolerant practices, water re-use capability, and use of agriculture for carbon sequestration are concepts that need to be integrated into a statewide water management program.

Recommendations:

• The Department, as well as other local, state, national, and international groups and organizations, are studying climate change to determine the proper path forward to address probable impacts. The integration of climate change with water policy is evolving on many fronts, although no single approach has emerged. A reliance on information sharing and collaboration among organizations would provide the most cost-effective and efficient approach at this time. The testimony at the public hearing emphasized that adaptive management will provide the Department with greater flexibility to evaluate agency policies, priorities, and resources. This will in turn enable the Department to more efficiently address and minimize increasing climate-related risks to water resources, including those that will directly affect water supply and wastewater systems. The causes of climate change and their relative contributions continue to be debated and models that project future trends and impacts continue to be refined. However, New Jersey does not have to wait for better models or more data to implement responsible changes to its water management programs. Common sense initiatives can be undertaken while awaiting improvements in predictive modeling.

Examples include:

1. Use of cost-effective adaptation strategies to identify, address, and minimize climaterelated risks to water supply, wastewater, and stormwater systems. Adaptive management strategies are needed that can cost-effectively address cross-functional issues. For example, integrating strategies for stormwater management and grey water re-use could address water demand, stormwater runoff and combined sewer overflows (CSO).

- 2. A statewide climate change adaptation plan, integrated with regional and national activities, should be developed and adopted. Smart growth planning concepts should be considered in concert with water management policies to ensure more effective implementation. All three components of water management supply, distribution, and treatment must be considered holistically.
- 3. Increase the flexibility of regulatory programs to enable them to respond more nimbly to changes in ambient conditions. Up-to-date information and trend analysis are critical to the timely identification of potentially critical impacts. Data of concern include water temperature, nutrients and metal concentrations, salinity, sea and flood levels; as well as a better understanding of the synergistic effects on water quality and aquatic life.
- **4. Develop incentives to stimulate investment** in mitigation, adaptation, and infrastructure needs. Needs assessments should incorporate the expected effects of climate change on the availability and quality of water resources, as well as on infrastructure. This should include planning and engineering costs associated with anticipated impacts.
- 5. Recognize the value of collaboration; make use of specialized skill sets. Many New Jersey organizations are poised to help state agencies with the tasks that lie ahead, including, those that participated in the December 2009 hearing. An open planning process engaging interested parties would leverage resources and result in a speedier response to the issues at hand. It can no longer be acceptable simply to react as problems become evident. New Jersey has the opportunity to proactively prepare now to respond to the future impacts from climate change.

The Department continues to participate in forums exploring adaptation to climate change impacts on water resources on state, regional, and national levels. The Department, as a participant on the USEPA National Water Program State-Tribal Climate Change Council, identified the following issues and priorities for waters of New Jersey:

1. Data, Information, Communication:

- Record monitoring data and activities in a format needed to support climate adaptation and mitigation discussions that are taking place.
- Take opportunities to get the message out and catalyze action.
- **2. Preparedness and Security:** Build a climate ready water utilities all-hazards approach to security preparedness.
- 3. Ground Water: Ground water quantity affected by climate processes.

4. Watersheds: Bring a watershed perspective to the discussion to incorporate water supply, drought, and floods as well as instream ecological concerns.

5. Wetlands:

- Identify specific practices for managing wetlands in response to sea level rise.
- Focus on vulnerable wetlands.

6. Energy Production Impacts:

- Geologic carbon sequestration (state/federal assessment legislation)
- Water needs for cooling energy-generating facilities
- 7. **Fisheries and Species:** Thermal impacts on streams create impacts for native populations and fishing.
- **8.** Impacts on Endangered Species (Flora and Fauna): including ecological impacts and ecological flow requirements.

Protection and maintenance of New Jersey's water resources from the impacts of climate change will require modification of the Department's monitoring and assessment programs, including:

- Monitoring to detect climate change impacts on waters of the State;
- Re-evaluation of designated and existing uses to assess attainability under climate-induced changes to ecological conditions;
- Re-evaluation of water quality standards and criteria to reflect changes in natural conditions due to climate-induced changes to aquatic ecosystems;
- Re-evaluation of funding and permitting priorities to address climate-induced threats to infrastructure, to promote more efficient water and wastewater facilities, and to expedite implementation of preventive and restorative measures that would mitigate adverse impacts of climate change on water resources.

Additional information on the Department's Climate Change program is available on the Department's Web site at https://www.nj.gov/dep/climatechange/.

Chapter 5: Water Pollution Control Programs

This chapter outlines the Department's approach and associated programs designed to protect, maintain, enhance, and restore water quality and to ensure the protection of ecological and public health in all waters of the State. This overarching goal serves as the foundation for the Department's water quality management programs. The purpose of the New Jersey Water Quality Planning Act (NJWQPA) is to restore, maintain, and preserve the quality of the waters of the State, including both surface and ground water, for the protection and preservation of the public health and welfare, food supplies, public water supplies, propagation of fish and wildlife, agricultural and industrial uses, aesthetic satisfaction, recreation, and other beneficial uses. The NJWQPA endeavors to achieve this purpose by instituting a Continuing Planning Process (CPP) broader in scope than that required under the federal Clean Water Act.

New Jersey's CPP is intended to integrate and unify statewide and areawide water quality management planning processes with other water quality programs and measures implemented by the Department, including statewide water quality monitoring and assessment, water quality standards development, TMDLs and discharge permitting, and develop a statewide implementation strategy to achieve the water quality standards and maintain, improve, and protect water quality throughout the State (see http://www.nj.gov/dep/wrm/docs/cpp.pdf). New Jersey statutes require comprehensive water resource management and planning that addresses issues such as land use and cumulative impacts to water resources, implementation of regulatory and non-regulatory approaches to environmental restoration, and consideration of environmental factors such as alteration of habitat, flow, substrate, climate, and tree canopy on aquatic life and other water resources.

The Department administers the CPP pursuant to the New Jersey Water Quality Management Planning rules at N.J.A.C. 7:15. The draft 303(d) List is proposed as an amendment to the Statewide Water Quality Management Plan pursuant to these rules and is adopted once it is approved by USEPA. Additional information is available on the Department's website at https://www.nj.gov/dep/wrm/index.html.

5.1 - Surface Water Quality Standards, Monitoring and Assessment

Surface Water Quality Standards

The <u>Surface Water Quality Standards (SWQS)</u>, N.J.A.C. 7:9B, establish the designated uses and <u>antidegradation</u> categories of the State's surface waters, classify surface waters based on those uses (i.e., stream classifications), and specify the water quality criteria and other policies and provisions necessary to attain those designated uses. Designated uses include water supply for drinking, agriculture and industrial uses, fish consumption, shellfish resources, propagation of fish and wildlife, and recreation. In addition, the SWQS specify general, technical, and interstate policies, and policies pertaining to the establishment of water quality-based effluent limitations.

The SWQS are used to develop regulatory requirements for other Department programs that will serve to protect the existing and designated uses of the State's surface waters. These programs include the New Jersey Pollutant Discharge Elimination System (NJPDES) program, Site Remediation Program, and various programs implemented by the Division of Land Use Regulation. The SWOS also form the basis for the Integrated Report. Waters that exceed SWQS require the development of total maximum daily loads (TMDLs), which represent the assimilative capacity of surface water for a given parameter of concern, or other alternative approaches to address the impairment. The Department has developed a Nutrient Criteria Enhancement Plan (NCEP) to explain the Department's approach to developing and enhancing the existing SWQS nutrient criteria and policies to protect designated uses of all New Jersey's surface

waters, including saline waters (estuarine and marine). The SWQS, including numeric and narrative criteria, classifications, antidegradation and other policies, are explained in more detail at http://www.state.nj.us/dep/wms/bears/swqs.htm.

Surface Water Quality Monitoring

Water quality monitoring supports the Department's efforts in developing and refining water quality standards, reporting on water quality conditions, listing impaired waters, issuing and enforcing discharge permits, managing nonpoint sources of pollution, protecting high quality waters, setting priorities for water quality restoration, tracking changes in water quality over time, and evaluating the effectiveness of restoration and protection actions necessary to achieve the federal Clean Water Act goal to "restore and maintain the chemical, physical and biological integrity of the Nation's waters". The Department operates the primary water quality monitoring networks for New Jersey, which are described in detail in the Department's Long Term Monitoring Strategy (see http://www.state.nj.us/dep/wms/longtermstrategyreport.pdf) and the Division of Water Monitoring and Standards website (see http://www.state.nj.us/dep/wms/bfbm/).

Water Quality Assessment

Both federal and state statutes require a routine assessment of statewide water quality to determine if existing and designated uses are fully supported, if any waters are impaired, and what actions are needed to restore water quality. The Department compiles all readily available water quality data and assesses it every two years to determine compliance with the SWQS. The results of this biennial assessment process are reported in the Integrated Water Quality Assessment Report (Integrated Report). The Integrated Report combines the reporting requirements of Sections 303(d) and 305(b) of the federal Clean Water Act and is submitted to USEPA for approval on a biennial

basis. The Integrated Report presents the results of statewide water quality assessment, including long-term water quality trends, support of designated uses, and causes and sources of water quality impairment.

The goal of the Integrated Report is to provide information needed to inform water resource managers, government officials, and the public about the overall health of the State's waters. This information can inform the New Jersey Pollutant Discharge Elimination System (NJPDES) program, Site Remediation Program, and various programs implemented by the Division of Land Use Regulation.

5.2 - Water Pollution Control - Regulatory Programs

The discharge of pollutants to waters of the State is regulated by the Department under the authority of the New Jersey Water Pollution Control Act (NJWPCA), N.J.S.A. 58:10A. The WPCA specifies, "No person shall discharge any pollutant except in conformity with a valid NJPDES permit." The Department implements the New Jersey Pollutant Discharge Elimination System (NJPDES) Program pursuant to the NJPDES regulations at N.J.A.C. 7:14A. The NJPDES Program protects New Jersey's ground and surface water quality by assuring the proper treatment and discharge of wastewater (and its residuals) and stormwater from various types of facilities and activities.

Total Maximum Daily Load Program

Total Maximum Daily Loads (TMDLs) represent the assimilative or carrying capacity of the receiving waterbody taking into consideration point and nonpoint sources of pollution, natural background water quality, and surface water withdrawals. A TMDL identifies the sources (point and nonpoint) contributing a pollutant of concern and sets load reductions needed to meet surface water quality standards. Waters that do not meet the applicable standards are placed on the 303(d) List of Water Quality Limited Waters (303(d) List). The 303(d) List is then ranked and prioritized for TMDL development.

Federal regulations concerning TMDLs are contained in USEPA's Water Quality Planning and Management Regulations (40 CFR 130,7(c)), and the New Jersey Water Quality Management Planning rules at N.J.A.C. 7:15-6. Section 303(d) of the federal Clean Water Act requires development of a TMDL for the pollutant(s) responsible for each impairment. The TMDL must be calculated so that standards will be attained, in consideration of critical conditions and seasonal variation, and must include a margin of safety (MOS) to account for uncertainty. The TMDL is allocated among all of the sources of the pollutant, including point sources, nonpoint sources, and natural background. Point sources are those regulated under the federal Clean Water Act, such as wastewater treatment facilities, combined sewer overflows and stormwater, and receive wasteload allocations (WLAs). Nonpoint sources (NPS) of pollution are diffuse sources, such as overland runoff and air deposition, which are not regulated under the federal Clean Water Act. NPS receive Load Allocations (LAs) as part of the TMDL. The MOS can be an explicit part of the TMDL equation or may be accounted for through conservative assumptions made in calculating the TMDL.

A TMDL implementation plan is developed to identify the measures needed to reduce loads from each identified source so that surface water quality standards can be attained. These measures include regulatory as well as non-regulatory actions. Regulatory measures typically include effluent limitations or other measures that are incorporated into NJPDES permits for wastewater or stormwater discharges. Non-regulatory measures include best management practices for agricultural land use and riparian restoration, as well as promotion of watershed/local stewardship activities such as construction of rain gardens and rain barrels. Additional information on TMDLs is available on the Department's website at https://www.state.nj.us/dep/wms/bears/tmdls.html.

NJPDES Permitting Program

Discharge to Surface Water Permits

The Department's NJPDES Discharge to Surface Water (DSW) Program regulates the discharge of treated and untreated effluent from various municipal and industrial facilities directly into surface waters of the State (e.g., rivers, streams, ocean waters) via a point source. These facilities operate under the authority of an individual or general NJPDES permit that limits the mass and/or concentration of pollutants discharged. The NJPDES DSW permits establish technology- or water quality-based effluent limitations that limit the mass and/or concentration of pollutants discharged to levels that will not cause the receiving water to exceed applicable surface water quality standards. Permitted discharges to surface water are required to submit monthly Discharge Monitoring Reports (DMR's) for Department review to determine compliance with effluent limitations. A facility that exceeds its effluent limitations or otherwise does not comply with its permit limits is referred to the Department's Division of Water Compliance and Enforcement for appropriate action pursuant to the New Jersey Clean Water Enforcement Act. Additional information about surface water discharge permits is available on the Department's website at http://www.nj.gov/dep/dwq/sw.htm.

Discharge to Ground Water Permits

The Department regulates facilities that discharge sanitary and industrial wastewater to ground water under the NJPDES Discharge to Ground Water (DGW) Permit Program. The pollution control requirements contained in NJPDES discharge to ground water (DGW) permits are those conditions necessary to restrict the discharge of pollutants to ground waters of the State so that they do not exceed applicable ground water quality standards. The types of facilities regulated include: mines, pits and quarries; schools and hospitals; potable water treatment plants; large corporate office buildings; industrial manufacturing facilities; campgrounds and mobile home parks; food processors; and sewage treatment plants and other discharges of wastewater that can impact ground water, including the management of dredged materials at upland locations. Additional information about the NJPDES DGW Permit Program is available on the Department's website at www.state.nj.us/dep/dwq/dgw_home.htm.

Stormwater Permits

New Jersey's Stormwater Permitting Program is divided into two sections: Industrial Stormwater Permitting ("Phase I") and Municipal Stormwater Regulation ("Phase II"). Both programs emphasize pollution prevention techniques and source control rather than "end-of-pipe" treatment. The program is implemented through the issuance of individual permits and general permits. These stormwater permits rely primarily on pollution prevention and best management practices (BMPs) that eliminate or minimize the contact between source materials and stormwater. Additional information about the Stormwater Permitting Program is available on the Department's website at http://www.nj.gov/dep/dwq/bnpc_home.htm and the Flood Hazard Control Act is located at https://www.nj.gov/dep/landuse/fha_main.html.

Significant Industrial Users

Some industrial dischargers discharge into a sanitary sewer system or publicly owned treatment works (POTW). The wastewater is conveyed to a local agency's treatment plant where it is treated and usually discharged into a river or stream. These dischargers are known as "indirect users." All direct users must comply with at least minimum regulatory requirements under N.J.A.C. 7:14A-21.2, as well as the rules and regulations or sewer use ordinance of the local agency. When this type of discharge meets one or more specific criteria, the discharger becomes a significant indirect user (SIU), and requires a permit. The Division of Water Quality's Bureau of Pretreatment and Residuals is responsible for issuing permits for SIUs discharging to POTWs.

Combined Sewer Overflow Program

Combined Sewer Systems (CSSs) are wastewater collection systems designed to carry sanitary sewage, industrial and commercial wastewater, and stormwater runoff in a single system of pipes to a publicly owned treatment works (POTW). During periods of rainfall or snowmelt, the total wastewater flows entering the collection system can exceed the capacity of the system or the treatment facility. Under such conditions, CSSs are designed to overflow at predetermined Combined Sewer Overflow Points and result in discharges of excess wastewater flows, known as Combined Sewer Overflows (CSOs), directly to surface waterbodies such as rivers, estuaries, and coastal waters.

CSOs are a human health concern because they can create the potential for exposure to disease-causing pathogens including protozoa, bacteria, and viruses. The National Combined Sewer Overflow Control Policy (National Policy) requires CSO permit holders to develop Combined Sewer Overflow Long Term Control Plans (CSO-LTCPs) that include the evaluation of alternatives for attaining compliance with the Clean Water Act, including compliance with surface water quality standards and protection of designated uses of waters of the state.

The Department is implementing a Statewide Combined Sewer Overflow Control Strategy consistent with the National Policy. As a first step, New Jersey has required its owners and operators of CSSs to develop and implement the Nine Minimum Control Measures (NMCs), specified in the National Policy. The CSO permit holders must capture and remove solids and floatables above a certain size at every CSO Point. It is estimated that New Jersey's CSO Solids/Floatables Control Facilities currently capture, remove, or otherwise prevent the discharge of

over 700 tons of solids and floatables materials per year. Additionally, over 60 CSO discharge points were eliminated since the onset of the program. More information on CSOs and the CSO-CTCPs is available on the Department's website at https://www.nj.gov/dep/dwq/cso.htm.

Stormwater Management

The Stormwater Management rules (N.J.A.C. 7:8) provide the basis for municipalities to develop stormwater management plans and specify stormwater management standards that are mandatory for new major development. The New Jersey Stormwater Best Management Practices Manual (BMP manual) has been developed to provide guidance to review agencies and the regulated community on complying with the standards in the Stormwater Management rules. The Stormwater Management rules also establish performance standards for ground water recharge to increase the integrity of the State's aquifers and protect dry weather base flow in streams. The rules require that 100 percent of the average annual ground water recharge be maintained for new development projects, to help mitigate future droughts and flooding.

In addition to recharge standards, the rules promote low impact development techniques by requiring consideration of non-structural design methods for stormwater management. Once nonstructural measures have been fully integrated into the site design, any remaining water quality concerns must be addressed using best management practices to reduce runoff of total suspended solids (TSS) by 80 percent and other pollutants up to the maximum extent feasible. Additional information about the Stormwater Management rules is available on the Department's website at http://www.njstormwater.org/.

Green Infrastructure

Traditional stormwater infrastructure design focuses on collecting and conveying rainwater off-site, so it is ultimately discharged into a downstream waterway. Green infrastructure mimics natural processes utilizing soils and vegetation to manage rainwater where it falls by allowing it to infiltrate into the soils, be taken up by plants, or stored for re-use as irrigation. Green infrastructure (GI) strategies reduce runoff volume by allowing rainfall to infiltrate into the soil where it can be used by plants or where it can recharge aquifers and stream base flow. Another way to reduce volume is to capture the rainfall in manufactured structures like rain barrels or cisterns where it is stored until it can be reused. Green infrastructure encourages the idea that stormwater is a resource that can be reused, rather than simply conveyed elsewhere. A comprehensive list of the Department's recommended green stormwater practices and completed projects is available on the Department's website at http://www.nj.gov/dep/gi/.

Soil Erosion and Sediment Control Act Implementation

The New Jersey Soil Erosion and Sediment Control Act is administered by the State's 15 Soil Conservation Districts (SCDs) and overseen by the NJDA to minimize soil erosion from construction sites, reduce nonpoint source pollution from sediment, and enhance water quality and stormwater quality. Conservation practices such as stormwater inlet protection, silt fencing, stabilized construction access, and temporary soil stabilization are just a few of many measures that

help reduce soil erosion on active construction sites. The SCDs review development and site plans and to ensure that they comply with standards established by the State Soil Conservation Committee pursuant to Chapter 251. SCDs also conduct a detailed review of Requests for Authorization (RfAs) to discharge stormwater from a developed site. Additional information about Chapter 251 and New Jersey SCDs is available on the NJDA website at http://www.nj.gov/agriculture/divisions/anr/nrc/conservdistricts.html.

Coastal Management Program

Concerted coastal management efforts began in New Jersey in 1970 with the passage of the Wetlands Act of 1970, N.J.S.A. 13:9A, followed by the Coastal Area Facility Review Act (CAFRA), N.J.S.A. 13:19, in 1973. In response to the 1972 passage of the federal Coastal Zone Management Act, New Jersey developed and gained federal approval of the New Jersey Coastal Management Program, which addresses the complex coastal ecosystem as a whole. The Coastal Management Program defines goals and standards for the purpose of integrating protection and enhancement of natural resources, appropriate land use and development, and public access to, and use of, New Jersey's coastal resources. The program, which was first approved in 1978, brings together the above laws as well as the Waterfront Development Law, the Freshwater Wetlands Protection Act, the Public Trust Doctrine for access to, and use of, state-owned tidelands, and the regulatory activities of the New Jersey Meadowlands Commission. These laws establish a set of over-arching policies that guide implementation of the New Jersey Coastal Management Program.

A primary mission of the Coastal Management Program is ensuring that coastal resources and ecosystems are conserved as a vital aspect of local, state, and federal efforts to enhance sustainable coastal communities. The coastal zone boundary of New Jersey encompasses the CAFRA Area and the New Jersey Meadowlands District. It also includes coastal waters to the limit of tidal influence, including the Atlantic Ocean (to the limit of New Jersey's seaward jurisdiction); Upper New York Bay, Newark Bay, Raritan Bay and the Arthur Kill; the Hudson, Raritan, Passaic, and Hackensack Rivers, and the tidal portions of the tributaries to these bays and rivers. The Delaware River and Bay, and other tidal streams of the Coastal Plain, are also in the coastal zone, as is a narrow band of adjacent uplands in the Waterfront Development Area outside of the CAFRA Area. Through the Coastal Management Program, the Department manages the State's diverse coastal zone, which includes portions of 17 counties and 245 municipalities. Additional information about New Jersey's Coastal Management Program, as well as the Assessment and the Strategy, are available on the Department's website at http://www.nj.gov/dep/cmp.

Residuals, Biosolids, Sewage Sludge

Residuals are generated by both domestic treatment plants (sewage sludge) and industrial treatment plants (industrial residuals). Residuals are managed in a variety of ways, including the development of Marketable Residuals Products (often referred to as biosolids) used to fertilize or condition the soil. Examples include pellets, compost, and alkaline materials. Residuals are also incinerated in New Jersey and managed in a variety of ways at out-of-state facilities. Beneficial use of residuals as a fertilizer or soil conditioner is regulated under a NJPDES permit. Incineration of residuals is regulated under New Jersey's Air Pollution Control Program (see the Department's website at

<u>http://www.nj.gov/dep/aqpp/</u>). Residuals managed in other states are regulated by the receiving state.

The Department oversees the Statewide Sludge Management Plan (a component of the Statewide Solid Waste Management Plan), and reviews and approves long-term generator residuals management plans. Through the implementation of the Sludge Quality Assurance Regulations (N.J.A.C. 7:14C), residuals generators must test their residuals and report the results to the Department on a regular basis. This data is available to assure compliance with the appropriate residuals management criteria in much the same way that the surface water program uses effluent data to assure compliance with wastewater discharge requirements. Additional information about residuals management available the Department's website is on http://www.state.nj.us/dep/dwq/sludge.htm.

5.3 - Water Pollution Control: Non-regulatory Programs

Nonpoint source (NPS) pollution is caused by precipitation moving over and through the land and carrying natural and synthetic pollutants into surface and ground water. The significance of NPS loadings can vary widely depending upon the watershed and the pollutant. NPS pollution is diffuse in origin, can emanate from anywhere in the watershed and is significantly associated with human activity. It is also not generally subject to regulatory controls. NPS pollution may include chemicals and pathogens such as oil and grease from roadways and parking lots; fertilizers from lawns, golf courses, and agricultural fields; and bacteria from improperly maintained septic systems, pet waste, and large congregations of waterfowl. Increased development can result in increased water withdrawals or loss of recharge of groundwater which can cause reduced base flow during dry weather and impair aquatic life and public water supply uses. Increased impervious cover can also increase stormwater runoff and exacerbate erosion of streambed and banks. This can significantly alter stream hydrology, increase turbidity and flashiness of streams, and increase flooding.

New Jersey Nonpoint Source Management Program

New Jersey's NPS Management Program is implemented cooperatively with many other Department programs along with other State agencies, including the New Jersey Department of Agriculture, local governments and the watershed associations. The program combines regulatory controls, non-regulatory strategies, watershed-based plans and restoration actions, and targeted funding to address NPS pollution on a scale that ranges from statewide to individual watersheds or sources of NPS. The NPS Plan is updated every five years and progress reports are published annually. Additional information about the Department's NPS Program is available on the Department's website at http://www.state.nj.us/dep/wms/bears/nps.htm.

Water Quality Restoration Grants for Nonpoint Source Pollution

The New Jersey Restoration Grants for Nonpoint Source Pollution is an integral component and funding source for statewide NPS management programs, which aim to control NPS pollution to achieve and maintain designated uses of waters of the State. This program's funding sources

include USEPA pass-through grants issued under <u>Section 319(h)</u> of the federal Clean Water Act (CWA) and other federal and State funds that may be available for NPS-related water quality restoration activities.

Each year, New Jersey announces the availability of grants along with a Request for Proposals (RFP) to solicit applications for projects eligible for the grant funds. The RFP serves as a guidance document that establishes criteria for projects based on federal requirements and state priorities; identifies specific administrative, procedural, and programmatic requirements for applicants; and provides timetables and deadlines for the grant application and related decision-making processes.

The accomplishments of the restoration grant program, including pollutant load reductions, are tracked through USEPA's Grant Reporting Tracking System (GRTS), which is available on USEPA's website at https://ofmpub.epa.gov/apex/grts/f?p=109:5000:::::. Additional information about the Department's Restoration Grants for Nonpoint Source Pollution is available on the Department's website at https://www.state.nj.us/dep/wms/bears/npsrestgrants.html.

Watershed Based Plans

Due to the diffuse nature of nonpoint source pollution, costs associated to address it, and the need for voluntary action, implementing NPS controls that will attain water quality standards often requires support from a coalition of stakeholders, coordination of programs, and availability of funding sources that will span multiple years. Watershed planning helps address water quality problems in a holistic manner by fully assessing the potential contributing causes and sources of pollution, then prioritizing restoration and protection strategies to address these problems.

Beginning in State Fiscal Year (SFY) 2006, the Department supported development of Watershed Restoration and Protection Plans, also referred to as Watershed Based Plans (WBPs), that focused on reducing NPS pollution. The Department issued Section 319(h) grants to fund planning and implementation of projects that would address water quality impairment through implementation of NPS pollution controls, including those specifically identified in approved total maximum daily load (TMDL) implementation plans, or necessary to address pollutants identified on an adopted 303(d) List of Water Quality Limited Waters. WBPs initiated after June 30, 2007 include the nine minimum components of a watershed plan set forth in the USEPA's "Handbook for Developing Watershed Plans to Restore and Protect Our Waters" (USEPA, 2005) to be eligible for Section 319(h) grant funds.

These nine minimum elements are:

- 1. Identify causes and sources of pollution
- 2. Estimate pollutant loading into the watershed and the expected load reductions
- 3. Describe management measures that will achieve load reductions and targeted critical areas
- 4. Estimate amounts of technical and financial assistance and the relevant authorities needed to implement the plan
- 5. Develop an information/education component
- 6. Develop a project schedule

- 7. Describe the interim, measurable milestones
- 8. Identify indicators to measure progress
- 9. Develop a monitoring component

AUs that are impaired by a parameter associated with NPS that is addressed under a WBPs are identified on Subpart 5R of the 303(d) List. As explained in Chapter 1, Subpart 5R identifies AUs impaired primarily by nonpoint sources of pollution that are not subject to regulation under the federal CWA, or regulated stormwater, which is most effectively addressed through source control. Watershed Based Plans can be an effective alternative to a TMDL to characterize pollutant sources, the reductions needed to attain standards, and the means to achieve the reductions.

Agricultural Nonpoint Source Pollution Control Program

The Department continues to foster a partnership with the New Jersey Department of Agriculture (NJDA), the United States Department of Agriculture - Natural Resources Conservation Service (USDA-NRCS), and other agricultural organizations to achieve New Jersey's water quality goals. In some of New Jersey's more rural watersheds, agricultural land uses are the major nonpoint source of pathogens and nutrients. Implementing best management and conservation practices on agricultural lands is an important component of New Jersey's nonpoint source pollution control strategy because it will improve water quality, conserve water and energy, prevent soil erosion, and reduce the use of nutrients and pesticides. The following are conservation programs that address nonpoint source pollution from agricultural activities.

Farm Security and Rural Investment Act (Farm Bill) Funding Programs

The USDA-NRCS provides technical and financial assistance to help farmers, ranchers, and forest landowners conserve soil, water, air, and other natural resources. All programs are voluntary and offer science-based solutions that benefit both the landowner and the environment. NRCS provides conservation technical assistance through their staff at NRCS Field Offices and through NRCS-certified Technical Service Providers, in cooperation with New Jersey's fifteen Soil Conservation Districts and the New Jersey Association of Conservation Districts. Other key partners include the NJDA, Rutgers University, and other State and Federal Agencies. New Jersey receives funds under the Farm Bill that are administered through the following USDA voluntary programs for eligible New Jersey landowners and agricultural producers (see descriptions below).

- <u>Agricultural Management Assistance (AMA):</u> provides cost share assistance to voluntarily address issues such as water management, water quality and erosion control.
- Agricultural Water Enhancement Program (AWEP): provides financial and technical assistance to agricultural producers in approved watersheds.
- Environmental Quality Incentives Program (EQIP): provides financial assistance for permanent measures or management strategies that address existing resource concerns.
- <u>Grassland Reserve Program (GRP)</u>: offers private landowners the opportunity to protect, restore, and enhance grasslands on their property.
- <u>Farm and Ranch Lands Protection Program (FRPP)</u>: provides matching funds to purchase conservation easements to keep productive farmland in agricultural uses.

- <u>Wildlife Habitat Incentives Program (WHIP):</u> provides financial assistance to create, enhance, or maintain five priority wildlife habitat types on nonfederal lands. Creation or improvement of wildlife habitat is generally as effective as buffers at controlling nonpoint source pollution.
- <u>Wetlands Reserve Program (WRP)</u>: provides technical and financial assistance to enhance wetlands in exchange for retiring marginal land from agriculture.
- <u>Conservation Security Program (CSP)</u>: rewards farmers who have demonstrated high levels of conservation and management on their farms by protecting soil and water quality.
- <u>Conservation Effects Assessment Project (CEAP)</u>: a national effort through which the NRCS works with the Department and other partners to monitor and quantify the effects and benefits of conservation practices.

Additional information about USDA-NRCS programs is available on the USDA website at http://www.nrcs.usda.gov/wps/portal/nrcs/main/national/programs/.

Farm Service Agency (FSA) Programs

NRCS provides technical assistance to applicants and contract holders working with the FSA Programs, which include the following:

Conservation Reserve Program (CRP): USDA's largest environmental improvement program on private lands allows producers to retire highly erodible or marginal cropland or pastureland and receive rental payments as well as financial assistance to convert the land to grass or trees. Cost sharing is provided to cover part of the cost to establish conservation measures on the land. This may include re-establishing native or perennial grasses, planting trees or fencing animals out of streams. Incentive payments are offered in some cases to encourage participation and to protect highly sensitive land surrounding waterways.

Conservation Reserve Enhancement Program (CREP): The New Jersey Departments of Environmental Protection and Agriculture, in partnership with the FSA and USDA-NRCS, signed an agreement in 2004 to help farmers reduce nonpoint source pollution caused by agricultural runoff in an effort to improve water quality in New Jersey. Under CREP, farmers receive financial incentives from the FSA and the NJDA to voluntarily remove marginal pastureland or cropland from agricultural production and convert the land to native grasses, trees and other vegetation. The vegetation can then serve as a buffer to filter or contain agricultural runoff and prevent polluted stormwater runoff generated by farms from reaching neighboring waterbodies. The enrollment of farmland into CREP in New Jersey is expected to improve stream health through the installation of water quality conservation practices on New Jersey farmland. Additional information on these and **FSA** programs available other is the FSA website at http://www.fsa.usda.gov/FSA/webapp?area=home&subject=copr&topic=landing.

Coastal Nonpoint Source Pollution Control Program

The Coastal Nonpoint Source Pollution Control Program (Section 6217 of the Coastal Zone Act Reauthorization Amendments of 1990) addresses NPS pollution in coastal waters. This program is administered jointly by the US Environmental Protection Agency (USEPA) and the National

Oceanic and Atmospheric Administration (NOAA). Section 6217 requires the 29 states and territories with approved Coastal Zone Management Programs to develop Coastal Nonpoint Pollution Control Programs (CNPCP). A CNPCP describes how a state will implement NPS BMPs to reduce pollution associated with several sources such as forestry practices, urban development, marinas and boating activities, hydromodification, and others. The Department has an approved CNPCP, a description of which may be found at http://www.state.nj.us/dep/cmp/czm_cnpp.html.

Floatables Control

The Department administers both the Clean Shores Program and the Adopt-A-Beach Program to address coastal debris. The Clean Shores Program uses inmates from state correctional facilities to remove wood and garbage from tidal shorelines. Cleaning up these wastes helps prevent the deleterious effects of marine debris upon recreational ocean bathing beaches and the coastal environment. The program is funded entirely from the sale of "Shore to Please" shore protection license plates. The sponsoring municipalities and state/federal parks provide support to the program and lay out the initial costs of the cleanup. The Clean Shores program in turn reimburses the sponsors for the cost of waste disposal and contracted services incurred during cleanup activities. The program is also responsible for building dune fencing and planting dune grass in oceanfront communities and state parks. In an average year, cleanups are carried out with the cooperation of more than 45 municipalities, seven county agencies, two state parks, one federal park, and the Department of Corrections. In 2010, the Clean Shores Program won the U.S. Environmental Protection Agency's Environmental Quality Award for demonstrating an outstanding commitment to protecting and enhancing environmental quality and public health. Additional information about Clean Shores Program available Department's website the on the at https://www.state.nj.us/dep/bmw/cleanshore.html.

The Adopt-A-Beach program fosters volunteer stewardship of the State's coastal beaches to reduce the threat of marine debris to marine fish and wildlife. The Department partners with the New Jersey Clean Communities Council and Clean Ocean Action to conduct the twice-a-year program. Participants are encouraged to adopt one of New Jersey's ocean beaches and become responsible for cleaning up debris and floatables that wash up on the shore. The cleanup results are forwarded to our national partner the Ocean Conservancy for analysis and inclusion in national and international marine debris databases. The results are used to gauge the type of education and outreach activities needed to change public attitudes and behavior about litter and the importance of keeping our waterways clean. Additional information about the Adopt-A-Beach Program is available on the Department's website at www.state.nj.us/dep//seeds/aabeach.htm.

Don't Waste Our Open Space Initiative

Illegal dumping on public land has been a growing problem in recent years throughout New Jersey. More than 170 publicly owned tracts are held in trust by the State of New Jersey, including 813,000 acres of state-preserved open space, parks, forests, wildlife management areas, natural lands, and preserves. Nearly all have been impacted by illegal dumping. Debris left behind by illegal dumpers is not only unsightly, but also potentially harmful to public health, wildlife, and ecosystems. Waste includes everything from cigarette butts, beverage containers and food wrappers to construction

debris, old TVs and computers, car parts and tires, refrigerators and even entire vehicles. Illegal dumping undermines volunteer community clean-up efforts and wastes taxpayer dollars on clean-ups costs.

The Department launched a new program in April 2014 to stop illegal dumping in state parks and natural lands that combines increased enforcement efforts with enhanced public education and outreach. The goal of the "Don't Waste Our Open Space" campaign is to crackdown on illegal dumping by raising public awareness and encouraging residents to get involved as stewards of public lands. The anti-dumping campaign is a coordinated effort involving several Department programs, including the State Parks Service, State Park Police, the State Forestry Service, the Division of Fish and Wildlife, Compliance and Enforcement, Solid Waste, Water Resources Management, and the Natural Lands Trust. Investigations of illegal dump sites on state properties, including a few involving motion-sensor camera discoveries, are conducted by State Park Police, Division of Fish & Wildlife's Conservation Officers, and Compliance & Enforcement staff. Activities and outcomes are posted on the Department's website at www.stopdumping.nj.gov, along with opportunities for local involvement. The progress of the "Don't Waste Our Open Space" pilot program will be evaluated after one year. If education and enforcement measures prove successful, it may serve as a model for county systems in New Jersey or other states throughout the Country.

5.4 - New Jersey Water Bank

The New Jersey Water Pollution Control Act requires the Department to inventory and rank needs, in order of priority, for the construction of municipal waste treatment works needed to meet water quality goals and standards. This requirement is satisfied by the New Jersey Water Bank (NJWB) formerly the New Jersey Environmental Infrastructure Financing Program. The NJWB is a revolving loan program administered by the Department and the New Jersey Environmental Infrastructure Trust (EIT), an independent state financing authority, pursuant to the New Jersey Wastewater Treatment Trust Act (58:11B-1 to 27), the Financial Assistance Programs for Wastewater Treatment Facilities rules and Wastewater Treatment Trust Procedures & Requirements (N.J.A.C. 7:22), and the Sewage Infrastructure Improvement Act Grants rules (NJAC 7:22A). The 1987 amendments to the federal Clean Water Act required states to establish a Clean Water State Revolving Fund (CWSRF) to provide financial assistance for the construction of projects that protect, maintain, and improve water quality. New Jersey's CWSRF program is included in the NJWB.

The NJWB provides loans to local government units for the construction of wastewater treatment facilities, sludge management systems for wastewater and water treatment systems, combined sewer overflow abatement, stormwater, and other nonpoint source management projects. The financing program also provides loans to both publicly, privately, and nonprofit noncommunity owned drinking water systems for the construction or upgrade of drinking water facilities, transmission and distribution systems, storage facilities, and source development. The NJWB finances projects by utilizing two funding sources. The Trust issues revenue bonds which are used in combination with zero percent interest funds to provide very low interest loans for water infrastructure improvements. The NJDEP administers a combination of Federal State Revolving

Fund (SRF) capitalization grants, as well as the State's matching funds, loan repayments, State appropriations and interest earned on such funds. Additional information about the New Jersey Water Bank is available on the Department's website at https://www.nj.gov/dep/dwq/mface_njeifp.htm

5.5 - Land Acquisition for Water Quality Protection

New Jersey has long recognized the importance of protecting headwater areas of rivers, streams, lakes, reservoirs, wetlands and coastal waters that safeguard our water supplies, natural resources, and provide outdoor recreational opportunities. These lands protect ecological resources and water quality, provide water-based recreational opportunities, and serve as linear open space linkages.

Water Bank

Land acquisition financed through the NJWB must demonstrate a water quality benefit. Preserving open space safeguards water supplies and other natural resources. The NJWB works closely with the Green Acres Program to maximize a community's limited funds for land acquisition. Public Law 2002, Chapter 76, directs the Green Acres State Land Acquisition Program to prioritize land for acquisition for the protection of water resources and flood prone areas. Pursuant to this legislation, Green Acres revised the ranking system used to evaluate state land projects based on water resource features, biodiversity, and other relevant factors. Additional information about Clean Water Financing for open space preservation is available on the Department's website at http://www.nj.gov/dep/greenacres/.

Green Acres/Blue Acres Program

The Green Acres Program was created in 1961 to meet New Jersey's growing recreational and conservation needs. As the principal land acquisition agent for the Department, Green Acres acquires land for state parks, forests, natural areas, and wildlife management areas. The Program also provides matching grants and low interest (two percent) loans to municipal and county governments, and matching grants to nonprofit organizations to acquire open space and develop outdoor recreational facilities. While the protection of water resources through land preservation has been a goal of Green Acres since its inception, the legislation further focuses Green Acres preservation efforts on lands that protect important water resources. In addition, Blue Acres acquires properties (including structures) that have been damaged by, or may be prone to incurring damage caused by, storms or storm-related flooding, or that may buffer or protect other lands from such damage. Additional information about New Jersey's Green Acres/Blue Acres Program is available on the Department's website at: http://www.nj.gov/dep/greenacres/.

5.6 - Source Water Assessment

The 1996 Amendments to the Safe Drinking Water Act required all states to establish a Source Water Assessment Program (SWAP). The purpose of SWAP is to provide for the protection and benefit of public water systems and to increase public awareness and involvement in protecting the

sources of public drinking water. New Jersey's SWAP Plan incorporates the following four fundamental steps:

- Determine the source water assessment area of each ground and surface water source of public drinking water.
- Inventory the potential contamination sources within the source water assessment area.
- Determine the public water system sources' susceptibility to regulated contaminants.
- Incorporate public education and participation.

Source water assessments provide the foundation for source water protection. Source water protection focuses on preserving and protecting the public drinking water source, particularly from the contaminants to which the source is most vulnerable, as identified in the source water assessments. The information developed from the SWAP provides communities with the tools necessary to begin protecting their valuable drinking water source. Additional information about the Source Water Assessment Program is available on the Department's website at http://www.nj.gov/dep/swap/index.html.

5.7 - Water Education and Engagement of Partners

In recognition that some water pollution problems, such as nonpoint source pollution, require approaches other than the traditional regulatory approach (i.e., discharge permits with numeric effluent limitations), the Department administers a cadre of regulatory programs and initiatives for water quality restoration, protection, and enhancement. In addition, some of the Department's water pollution control programs also employ non-regulatory elements, such as education and outreach, either in lieu of, or in tandem with, other permit requirements. The Department also administers a number of water-focused public education and outreach programs.

AmeriCorps NJ Watershed Ambassadors Program

The New Jersey Department of Environmental Protection began hosting the AmeriCorps New Jersey Watershed Ambassadors Program (NJWAP) in September of 2000 under an AmeriCorps State contract with the Corporation for National and Community Service. By working with local communities, the NJWAP promotes capacity building by raising public awareness about water quality and watershed issues through direct community involvement. AmeriCorps members are each assigned to one of New Jersey's 20 Watershed Management Areas (WMA) and work with "host" agencies to serve as "Watershed Ambassadors" to their watershed communities. Additional information about the NJWAP, along with a current list of ambassadors and host agencies, is available on the Department's web page at http://www.nj.gov/dep/wms/bears/americorps.htm.

AmeriCorps NJ Watershed Ambassadors train and work with community volunteers to monitor the waters in their community using state and federally-approved visual and biological monitoring techniques. AmeriCorps New Jersey Watershed Ambassadors also visit schools and community organizations to share information and educate the community about water and watershed issues in New Jersey and to encourage students and residents to become involved in protecting their

watershed. The Program works to improve water quality by exploring relationships between people and the environment, nurturing community-based environmental activities, and empowering residents to make responsible and informed decisions regarding their watershed to reduce NPS pollution.

Each year, the NJWAP commits to completing a set of objectives that serve to raise awareness of the importance of individual actions in controlling NPS, build capacity at the local level to assess water quality condition and directly accomplish source control projects. The objectives may be revised from year to year but remain focused on NPS control.

Community Water Monitoring Program (Citizen Science and Volunteer Monitoring)

An important element of non-regulatory NPS control is the cumulative effect of the actions of citizens within their communities. Citizens practice water conservation and participate in stream walks, beach cleanups, and other environmental activities sponsored by community-based organizations. By helping out in such efforts, citizens address New Jersey's largest water quality problem, nonpoint source pollution, advancing the goal of making more of our rivers, lakes, and coastal waters safe for swimming, fishing, drinking, and aquatic life.

The Department's Community Water Monitoring Program https://www.state.nj.us/dep/wms/bears/comm water monitoring.htm is the collection of scientific water quality data by concerned citizens working in partnership with professional scientists and government decision-makers. This valuable data helps determine the ecological condition of local waterbodies as well as identify the causes and sources of water quality impairment. Community water monitoring includes both "citizen science" and "volunteer monitoring" activities. The Program provides opportunities for community engagement through the collection of scientific data that helps determine the ecological condition of local waterbodies, as well as causes and sources of impairment. The information provided by citizen volunteers enables the Department to better understand and evaluate what is happening in watershed and assists policy officials in making more informed decisions to protect public health, conserve sensitive habitats, and preserve the integrity of New Jersey's waterways.

The goal of the Department's Community Water Monitoring Program is twofold. First, it strives to support those organizations whose volunteers are monitoring local streams, rivers, and lakes and collecting data for use locally or for inclusion in the Integrated Report, supplementing the Department's networks. Second, the Program anticipates calling upon such organizations and other volunteers to assist the Department collect data for specific research, monitoring and assessment initiatives.

Multiple New Jersey-based resources are available to support community water monitoring. The Department has contracted with <u>Watershed Institute</u> to support a statewide community water monitoring network to oversee the coordination of existing, and creation of new, community-based water quality monitoring programs in new Jersey. To build capacity and partnerships via workshops, trainings, sharing best practices and lessons learned as well as providing small grants across the community. Additional information and assistance may be found at their website,

https://thewatershed.org/. AmeriCorps NJ Watershed Ambassadors and members of the New Jersey Water Monitoring Council also serve as resources for community water monitoring activities

Citizen scientists have been and will continue to be called upon to assist with key program initiatives. The model for this was the intensive monitoring program undertaken in support of the Barnegat Bay 10 Point Action Plan. Going forward, a specific geographic area or resource may be targeted by the Department for further research or data collection. Under this template, the Department anticipates the need for additional resources and staff to accomplish targeted monitoring and will call upon its partners, including the volunteer monitoring programs, to be the "boots on the ground" locally collecting data, monitoring existing or changing conditions and reporting to the Department. Participating by volunteers in these citizen science projects can provide critical data that are then used for water resource protection, conservation, and restoration efforts.

Other Departmental education and outreach programs aimed at improving water quality are:

- The <u>Clean Water Rangers</u> publications offer educators free teaching materials and other resources for their students as well as background information on watersheds and nonpoint source pollution.
- "Project WET" (Water Education for Teachers at http://www.projectwet.org/) is an international program that offers teachers a better understanding of the world's water resources through hands-on, multi-disciplinary lessons. Through teacher workshops on multiple curriculum activity guides related to water resources, NJ Project WET teaches about the importance and value of water in our everyday life while offering specialized programs about New Jersey's water resources and watersheds.
- The Urban Watershed Education Program educates young students living in New Jersey's urban estuaries about the hazards of eating contaminated fish and helps them to enjoy and respect their local water resources by focusing on healthier fishing and shell fishing alternatives in their community. This intensive four-day program gives students the opportunity to experience their local waters first-hand through storm drain marking, water monitoring, aquatic biology, and fishing activities. (See https://www.nj.gov/dep/wms/bears/urban_fishing.htm for more information.)
- Clean Water New Jersey is aimed at reducing nonpoint source pollution carried by stormwater runoff by encouraging New Jersey citizens to change behavior that results in water pollution. The campaign includes television commercials, radio ads, posters, a website, and educational brochures. The Clean Water NJ website (www.cleanwaternj.org) provides information to the general public about "stormwater pollution" and what citizens can do to help reduce it in their homes, cars, and communities. The website also provides links to educational resources for teachers and for the general public.

• <u>"SEEDS"</u> is the Department's nationally acclaimed website, the "State Environmental Education Directory", which provides educational materials and links to additional educational resources on many environmental topics, including water pollution, conservation, and stewardship. Additional information about SEEDS is available on the Department's website at http://www.nj.gov/dep/seeds.

5.8 - Regional Water Quality Initiatives

A number of regional initiatives have been formulated to address issues important within those regions. Planning, regulatory, and non-regulatory measures aim to identify and respond to water quality issues in each:

- **Highlands Region Water Resource Protection Program:** The purpose of the Highlands Water Protection and Planning Act (Highlands Act) is to preserve an essential source of clean and plentiful drinking water for one-half of the State's population, and to protect the State's great diversity of natural resources. The Highlands Act establishes a Highlands Preservation Area (Preservation Area) and a Highlands Planning Area (Planning Area), each of roughly 400,000 acres. Additional information about the Highlands Act and its implementation is available on the Department's website at http://www.nj.gov/dep/highlands/.
- Pinelands Protection Program: The Pinelands National Reserve (PNR) was created by Congress under the National Parks and Recreation Act of 1978. The PNR is the first National Reserve in the nation. The PNR encompasses approximately 1.1 million acres covering portions of seven counties and all or parts of 56 municipalities. The Pinelands Preserve occupies 22% of New Jersey's land area. It is the largest body of open space on the Mid-Atlantic seaboard between Richmond and Boston and is underlain by aquifers containing 17 trillion gallons of some of the purest water in the land. The Pinelands Comprehensive Management Plan sets forth the regulations and standards designed to promote orderly development of the Pinelands so as to preserve and protect the region's significant and unique ecology and natural resources. The Plan is administered by the New Jersey Pinelands Commission. Additional information is available on the Pinelands Commission website at http://www.state.nj.us/pinelands/index.shtml.
- Barnegat Bay Partnership (BBP): The Barnegat Bay Partnership (BBP), operates the Barnegat Bay National Estuary Program and is a partnership of federal, state, and local interests overseeing the development and implementation of a management plan for the entire Barnegat Bay watershed. Additional information about the Barnegat Bay Partnership (BBP), including actions, projects, programs, and publications, is available on the BBP website at http://bbp.ocean.edu.
- The Delaware Estuary Program (Partnership for the Delaware Estuary): The Delaware Estuary Program activities are coordinated by the Partnership for the Delaware Estuary (PDE). The PDE is charged with addressing the full complement of actions called for in the CCMP. Additional information about the Partnership for the Delaware Estuary (PDE), including

actions, projects, programs, and publications, is available on PDE's website at www.DelawareEstuary.org.

• New York/New Jersey Harbor Estuary Program (HEP): The primary focus of the New York/New Jersey Harbor Estuary Program (HEP) is on the core area of the Harbor. Additional information about the New York/New Jersey Harbor Estuary Program (HEP), including actions, projects, programs, and publications, is available on the HEP website at https://www.hudsonriver.org/estuary-program.

5.9 - New Jersey's Wetlands Protection Program

In New Jersey, the chemical, physical, and biological integrity of wetlands is protected under both federal and state laws. Federal protection is provided under sections 303, 401, and 404 of the federal Clean Water Act (the Act). Section 303 provides protection through the antidegradation provisions of the Surface Water Quality Standards. (New Jersey's Surface Water Quality Standards include wetlands in the definition of "surface waters". When USEPA approves the state standards, they become the federal standards for state waters.) Section 401 is designed to allow the state to control any discharges to its waters that may result from the issuance of a federal permit or license, through a certification process. Section 404 addresses and regulates the discharge of dredge and/or fill material into wetlands and other waters of the state. In 1994, New Jersey began implementing its state program in place of the Section 404 program after being granted the authority by USEPA pursuant to Section 404(g) of the Act.

New Jersey has taken a multi-faceted, comprehensive, approach to managing and protecting freshwater and coastal wetlands and developed the New Jersey Wetland Program Plan 2019-2022. This four-vear Wetland Program https://www.nj.gov/dep/dsr/wetlands/New%20Jersey%20Wetland%20Program%20Plan%202019-2022 Full%20Report.pdf is an update of the first Plan developed in 2013 and provides a framework for the State of New Jersey to strengthen the core elements of its wetland program and to continue to reach identified goals. The steps outlined in the plan will serve to direct current and future wetland protection and management efforts along a coordinated path to the benefit of New Jersey's wetland resources and the quality of life for future generations. Additional information about the **Programs** Department's Wetlands is available on Department's website the https://www.nj.gov/dep/landuse/fww/fww main.html.

Wetlands Monitoring, Assessment and Research

The Department, in collaboration with Rutgers University, has been undertaking research focusing on quantitative wetland biological assessment methods. A goal of this research is to explore development of a wetlands index of biotic integrity (IBI) for New Jersey. To date, research has focused on riparian forested wetlands, primarily vegetative species, and macroinvertebrates, including possibly linking to the Department's macroinvertebrate monitoring network for streams.

Long-term monitoring of coastal wetlands in Barnegat Bay and the Delaware Estuary is being conducted by the Partnership for the Delaware Estuary, Academy of Natural Sciences of Drexel University, Barnegat Bay Partnership, and the USFWS. Surface Elevation Tables (SET) and associated wetland assessments utilizing the Mid-Atlantic Tidal Rapid Assessment Method (MidTRAM) are being employed at several sites along the coast to assess the impacts of rising sea level on tidal marsh integrity.

The Department's Coastal Management Program established a Coastal Shoreline Resiliency Program to prioritize and implement ecological restoration and protection of coastal wetlands including the creation of living shorelines to protect vegetated shorelines, beaches, and habitat in the littoral zone of coastal waterways from the effects of erosion due to sea level rise and storm surges.

5.11 - Water Compliance and Enforcement

The Department's Division of Water Compliance and Enforcement is responsible for ensuring compliance with the State's water programs, with a particular focus on inspections of wastewater discharge and drinking water supply facilities. The Department employs site inspections and detailed reviews of reported information to ascertain compliance and takes administrative actions, levies penalties, and where necessary, works cooperatively with criminal prosecutors, to ensure compliance.

In 1990, the Legislature enacted substantial amendments to the Water Pollution Control Act (WPCA), commonly known as the Clean Water Enforcement Act, P.L. 1990, c. 28 (CWEA). The CWEA requires the Department to inspect permitted facilities and municipal treatment works at least annually. The CWEA requires the Department to submit a report on the implementation of the CWEA's requirements to the Governor and the Legislature by March 31 of each year. Copies of these **CWEA** reports available the Department's website are on http://www.ni.gov/dep/enforcement/report-cwea.html. Additional information about the Water Compliance and Enforcement is also available on the Department's http://www.nj.gov/dep/enforcement/water.html.

5.12 - Water Quality Assurance Program

The Office of Quality Assurance (OQA) administers the Department's Quality Assurance Program, which is required by USEPA to ensure that environmental data used by the Department is generated, compiled, and reviewed using specific quality assurance/quality control (QA/QC) procedures. OQA is responsible for developing and implementing the Department's Quality Management Plan (QMP), which defines the Department's mission and planned quality assurance work outputs for the forthcoming fiscal years. The QMP documents the Department's environmental principles and objectives, organizational responsibilities, and policies and procedures for the generation, compilation, review, and use of data of documented quality. OQA is also responsible for certifying that the laboratories that analyze data used by the Department operate using appropriate quality control measures and analytic methods. Certification is offered through

both the State Environmental Laboratory Certification Program and the state-run National Environmental Laboratory Accreditation Program.

5.13 - Ground Water Quality Monitoring and Protection Programs

While the focus of the federal Clean Water Act is the protection of surface waters, New Jersey's Water Quality Planning Act and Water Pollution Control Act explicitly require protection of ground water quality, primarily as a source of potable water supplies. The primary goal of New Jersey's ground water quality programs is to provide safe drinking water, as required under the federal Safe Drinking Water Act (see also Source Water Protection Programs).

Ground Water Quality Standards

The New Jersey <u>Ground Water Quality Standards (GWQS)</u>, <u>N.J.A.C 7:9C</u>, establish the designated uses of the State's ground waters, classify ground waters based on those uses, and specify the water quality criteria and other policies and provisions necessary to attain those designated uses. Ground water is classified according to its hydrogeologic characteristics and designated uses. Designated uses are assigned as primary or secondary uses of ground water and include maintenance of special ecological resources, provision of, and conversion to potable water, agricultural and industrial water supply, and other reasonable uses. The GWQS also establish antidegradation policies (see N.J.A.C. 7:9C-1.8), which are designed to protect the existing and designated uses of the State's ground waters.

The GWQS provide the objectives for regulatory and non-regulatory actions to protect and restore ground water quality. Ground water quality criteria are derived using the same human health risk assessments as drinking water maximum contaminant limits established pursuant to the federal Safe Drinking Water Act. More detailed information about the GWQS is available on the Department's website at http://www.state.nj.us/dep/wms/bears/gwqs.htm.

Ground Water Quality Monitoring

The Ambient Ground Water Quality Monitoring Network (AGWQMN) is a cooperative effort by the Department and USGS that monitors and provides information about land use-related nonpoint source contaminant effects on shallow ground water quality in the New Jersey. This information is important because this water recharges deeper aquifers used for potable water supplies and provides base flow to local streams and wetlands. The New Jersey Geological Survey (NJGS) is responsible for network design, well installation, well maintenance, collection of ground water samples, interpretation of data, and publication of reports.

In addition to ambient ground water quality, the Department also conducts sampling of private wells pursuant to the New Jersey Private Well Testing Act. New Jersey requires sampling of private wells when property is sold or leased. Wells statewide are required to be tested for bacteria (total coliform, fecal coliform, and *E. coli*), nitrates, lead, arsenic, gross alpha, uranium, mercury, pH, iron, manganese and 26 volatile organic compounds. All samples are raw water collected prior to any treatment. More details, along with monitoring results, are provided in Appendix F.

5.14 - Air Quality Control

Airborne pollutants from human and natural sources can deposit back onto land and waterbodies, sometimes at great distances from the source, and can be an important contributor to declining water quality. Pollutants in waterbodies that may originate in part from atmospheric sources include nitrogen compounds, sulfur compounds, mercury, pesticides, and other toxics. Both human and natural processes can lead to air pollution. Human sources include the combustion of fossil fuels for power generation and transportation, the release of chemical byproducts from industrial and agricultural processes, and the incineration of waste. Natural processes that can release substantial amounts of pollutants into the air include volcanoes and forest fires.

Airborne pollution can fall to the ground in precipitation, in dust, or simply due to gravity. This type of pollution is called "atmospheric deposition" or "air deposition". Pollution deposited from the air can reach water bodies in two ways. It can either be deposited directly onto the surface of the water (direct deposition) or be deposited onto land and be carried to water bodies through run off (indirect deposition). Once these pollutants are in the water, they can have undesirable health and environmental impacts, such as contaminated fish, harmful algal blooms, and unsafe drinking water.

Addressing water quality impacts from atmospheric deposition of toxics and nitrogen is an increasingly important challenge since these pollutants can adversely impact both human health and the environment. Atmospheric deposition is a major contributor to the overall loading of mercury to U.S. waters. Nationally, mercury is the most frequently listed reason for fish consumption advisories. As of December 1999, 41 States had issued fish advisories for mercury. Additionally, atmospheric deposition of nitrogen contributes to eutrophication in a significant number of our coastal watersheds. According to EPA, roughly 10-40% of the nitrogen that reaches East and Gulf Coast estuaries is transported and deposited via the atmosphere.

Chapter 6: Cost/Benefit Assessment

Although the value of water quality protection is hard to quantify, it is obvious that water quality conditions impact the dollars expended on water-related activities such as recreational boating, swimming, and fishing; dollars generated by commercial fisheries, including shellfish, and the seafood industry; as well as the economic benefit generated by jobs, housing, retail sales, and tourism associated with these industries. Good water quality provides economic benefits associated with recreation, tourism, and marine industries, as well as the resultant tax revenues, and reduces the costs of treatment required to meet drinking water standards for potable water supplies; therefore, protecting, restoring, and maintaining water quality in all our waterways has a direct and positive impact on the State's economy.

It is important for New Jersey's aquatic ecosystems to flourish and persevere over time as well. Aquatic ecosystems provide several long-term economic benefits to society, including ecosystem

"services" such as temporary storage of floodwaters by wetlands, water purification from wetlands, and numerous others. In 2007, the Department estimated the economic value of New Jersey's aquatic ecosystems at more than 19 billion dollars (see Table 5.1).⁵⁷ These estimated values make it clear that water of a quality and quantity sufficient to support these ecosystems in a state of healthy functioning is an essential part of a natural environment that provides extremely large economic benefits to New Jersey.

| Ecosystem Type | Total Acres as of 2002 | Ecosystem Service Value (2009 \$/acre/yr) | Ecosystem Service Value (2009 \$/yr) |
|-----------------------|------------------------|--|---|
| Freshwater wetlands | 814,479 | \$13,141 | \$10,703,270,530 |
| Estuaries | 455,700 | \$13,238 | \$6,032,469,106 |
| Saltwater wetlands | 190,520 | \$6,965 | \$1,326,936,744 |
| Coastal shelf | 299,835 | \$1,476 | \$442,455,715 |
| Beaches/dunes | 7,837 | \$47,879 | \$375,227,660 |
| Open fresh water | 86,232 | \$869 | \$74,939,057 |
| Riparian buffers | 15,146 | \$3,842 | \$58,190,205 |
| Total | 1,869,749 | | \$19,013,489,018 |

Table 5.1: Annual Ecosystem Service Values for Aquatic Ecosystems in New Jersey

In 2008, the Department estimated the cost of protecting New Jersey's water resources from nonpoint sources alone as more than 17 billion dollars – the highest in the nation. In 2012, the Department calculated over 21 billion dollars in total clean water needs for New Jersey. These numbers were derived from the Clean Watersheds Needs Survey (CWNS) conducted every four years pursuant to CWA Sections 205(a) and 516. The CWNS is a comprehensive assessment of the capital needs required to meet the CWA's water quality goals. Under the CWNS, USEPA and states collect information about publicly owned wastewater collection and treatment facilities, stormwater and combined sewer overflows (CSOs) control facilities, nonpoint source (NPS) pollution control projects, and decentralized wastewater management. This information includes estimated needs (costs) to address water quality impairment or public health concerns related to water quality. USEPA compiles the CWNS results to document national needs in its Report to Congress. The report provides Congress, as well as state legislatures, with information to assist their budgeting efforts. The data are also used to help measure environmental progress, provide information to the public, and to assist local and state governments implement water quality programs.

New Jersey's 2008 CWNS utilized the Innovative Method option offered by USEPA. This approach included: demonstrating needs utilizing TMDLs, 303(d) Listings, and regulations; choosing best management practices (BMPs) appropriate to address the identified needs (i.e., constructed wetlands, porous pavement, peak reduction, rain gardens and Special Water Resource

_

⁵⁷ NJDEP. <u>Valuing New Jersey's Natural Capital</u>: An Assessment of the Economic Value of the State's Natural Resources. April 2007. http://www.nj.gov/dep/dsr/naturalcap</u>. Table 7.1 is based on data from Table 4 of Part II this report. Dollar amounts were converted from 2004 to 2009 dollars using the change in the Consumer Price Index for All Urban Consumers published by the U.S. Department of Labor's Bureau of Labor Statistics at http://www.bls.gov/cpi/.

Protection Area projects); determining an eligible cost for each BMP (USEPA required three actual costs or engineering estimates for each BMP); and applying the needs/costs statewide. USEPA required that information and costs be provided on a HUC 14 subwatershed basis, based on appropriate land uses. Regional costs were adjusted by utilizing location factors. Additional information about the CWNS is available on USEPA's website at http://water.epa.gov/scitech/datait/databases/cwns/index.cfm and at the Department's website at: http://www.nj.gov/dep/dwq/cwns.htm.

For the 2012 Clean Water Needs Survey results for New Jersey, the largest cost percent was associated with total wastewater treatment and conveyance needs as well as combined sewer overflow needs at 42% or 16.8 billion dollars. While these cost estimates may seem overwhelming, the economic benefits, as documented above, far outweigh the costs, as shown in Table 7.1. Improved water quality, achieved through the investments identified in the CWNS, will result in an increase in the number of recreational freshwater fishing licenses issued by the State, increased marine fishing and shellfish harvesting, and a decrease in closures at New Jersey's ocean and bay beaches; all of which provide economic benefits associated with recreation, tourism, and marine industries, as well as the resultant tax revenues. The reduction in combined sewer overflows discharge to New Jersey's waterbodies will improve both aquatic life and recreational designated uses of these waters. The Clean Water Needs Survey is made final upon USEPA's submittal of their *Report to Congress*.

Additional economic benefit is realized from the natural services that help protect and maintain water quality in New Jersey's, including wetlands; marine ecosystems; forests; urban green space; beaches and dunes; agricultural land, cropland, and pasture; and open fresh water and riparian buffers, all of which contribute to ecosystem services ("ecoservices") such as temporary storage of flood waters by wetlands, long-term storage of greenhouse gases in forests, dilution and assimilation of wastes by rivers, recreational opportunities, and numerous others. All of these services provide economic value to society and offset the significant costs borne for their protection.
