Vaccine Preventable Disease Program

2022 POLIO CASE IN THE UNITED STATES:
WHAT YOU NEED TO KNOW
Date: October 5, 2022

POLIO SITUATION UPDATE

In late July 2022, a case of paralytic poliomyelitis, caused by vaccine-derived poliovirus type 2, was confirmed in an unvaccinated adult in Rockland County, New York. The infection was not travel-related. One case of paralytic polio is considered an outbreak. Poliovirus has been detected in samples of sewage water in several New York locations, indicating local circulation of poliovirus. This document has been revised to reflect updated CDC recommendations regarding adult polio vaccination (as of September 22, 2022). All children and adolescents who are unvaccinated or under-vaccinated should be brought up to date with all routine CDC-recommended inactivated polio vaccine (IPV) doses. Adults (18 years of age and older) who are unvaccinated or under-vaccinated and at increased risk of infection should receive polio vaccination as recommended by the CDC. This is particularly important if they live, work, attend school, or have frequent social interactions with communities in areas where poliovirus has been repeatedly detected in wastewater (sewage), including Orange, Rockland, and Sullivan counties; these groups are considered to be at greater risk for exposure to polioviruses than the general population.

Prevention: Protect Your Patients with Vaccination

As a bordering state, the circulation of poliovirus in parts of New York State underscores the urgency of making sure that every child and adult in New Jersey has been vaccinated against polio. Three doses of polio vaccine are 99% effective in preventing paralysis.

All New Jersey providers who are capable of administering vaccines in their practice should consider stocking inactivated polio vaccine (IPV) and offer IPV to patients according to the recommendations below, which are consistent with guidelines from the Advisory Committee on Immunization Practices (ACIP) available at https://www.cdc.gov/mmwr/preview/mmwrhtml/rr4905a1.htm.

Combination vaccines including IPV can be given to children and is preferred as appropriate, according to ACIP guidelines. IPV alone can be given to children and adults and is available through your usual vaccine ordering channels or may be available from the local health department.
In view of misinformation and rumors spreading in the involved areas, we strongly encourage healthcare providers, who tend to be highly trusted, to speak out about the reality of the threat of poliovirus. We urge you to immediately identify and schedule appointments for unvaccinated or under-vaccinated children to receive the IPV.

Particular emphasis should be placed on catch-up immunization for young children who are unimmunized or under-immunized, such as those whose parents might have planned to delay immunization until shortly before school enrollment. The hygiene habits of young children and the fact that they are often cared for in congregate settings place them at greater risk for acquiring poliovirus.

### Polio Vaccination Recommendations

Polio immunization has been available since 1955 and has been part of the routine childhood immunization schedule for decades. The IPV is the only polio vaccine that has been given in the United States since 2000 and protects against all three types of poliovirus, regardless of whether it was given in the U.S. or abroad. Generally, those who attended school in NJ would likely have received polio vaccine as part of school-entry requirements. These recommendations have been revised based on CDC’s September 22, 2022, updated recommendations clarifying adult polio vaccination.

For persons with a record of oral polio vaccine (OPV), only trivalent OPV (tOPV) counts toward fully vaccinated status.

- **Doses of OPV given before April 1, 2016, should be counted** unless specifically noted as monovalent, bivalent, or as given during a poliovirus immunization campaign.

- **Doses of OPV given on or after April 1, 2016, should not be counted.**
  - OPV given on or after April 1, 2016, as part of routine immunization regimens outside the U.S. does not protect against type 2 poliovirus, which is the type circulating in New York.
  - If there is uncertainty about whether a dose of OPV should be counted, give a dose of IPV.

**Children:**

- **Four doses of polio vaccine, one dose at each of the following ages:**
  - 2 months old
  - 4 months old
  - 6 through 18 months old
  - 4 through 6 years old

**Adults:**

- **At increased risk of infection and unvaccinated, incompletely vaccinated, or unknown vaccination status:** should complete the primary series:
  - Two doses separated by 1 to 2 months, and
  - A third dose 6 to 12 months after the second dose.
• **Not at increased risk of infection and unvaccinated, incompletely vaccinated, or unknown vaccination status:** should discuss with their provider to understand their individual risk for polio and need for polio vaccination.

• **Fully vaccinated** (completed 3 or more doses of polio vaccine in the past): may receive a one-time booster dose of IPV if at increased risk for exposure to poliovirus
  - At this time, booster doses are not recommended for individuals visiting the New York City metropolitan area, including Orange, Rockland, and Sullivan Counties, merely because of their travel status.

**Increased risk includes:**

• Unvaccinated or incompletely vaccinated adults living or working in a community where poliovirus is circulating.
  - Areas considered to have **community transmission** of poliovirus include those where poliovirus has been repeatedly detected in wastewater (currently Rockland, Orange, and Sullivan Counties).

• Laboratory and healthcare workers who handle specimens that might contain polioviruses.
  - This may include individuals who collect or work with wastewater specimens for poliovirus testing.

• Healthcare providers or other caregivers who have close contact with a person who could be infected with poliovirus, specifically within areas with community transmission of poliovirus (as described above):
  - Healthcare workers who could care for patients with poliovirus (e.g., urgent care, emergency department, neurology, virology laboratory workers)
  - Individuals who will or might have close contact with a person known or suspected to be infected with poliovirus or such person’s household members or other close contacts of a case or suspect case
  - Childcare or pre-Kindergarten providers who provide diapering or toileting care or assistance

• Travelers who are traveling to areas or countries where polio is epidemic or endemic. Since the situation is dynamic, refer to the CDC pages for the most up-to-date travel-related polio vaccine recommendations:
  - Travelers’ Health for destination pages
  - Polio: For Travelers

• Unvaccinated or incompletely vaccinated adults whose children will be receiving oral poliovirus vaccine (for example, international adoptees or refugees).

**Travel:**

Polio vaccination is recommended for all travelers to countries with wild poliovirus or vaccine-derived poliovirus circulation. People who plan to travel internationally should make sure they and their children are up-to-date with all their vaccines including polio before departure. For more information see [Polio: For Travelers | CDC](https://www.cdc.gov/polio/) and [CDC Travel Destinations List](https://www.cdc.gov/travel/).
Evidence of Immunity to Poliovirus

**Previous poliovirus infection**: Poliovirus infection can provide lifelong immunity against the disease, but this protection is limited to the particular type of poliovirus involved (Type 1, 2, or 3). Infection with one type does not protect an individual against infection with the other two types.

**Serology**: Please note, serology to assess immunity for people with no or questionable documentation of poliovirus vaccination is not recommended because of increasingly limited availability of antibody testing against type 2 poliovirus. More information is available at: [https://www.cdc.gov/mmwr/volumes/66/wr/mm6601a6.htm](https://www.cdc.gov/mmwr/volumes/66/wr/mm6601a6.htm)

**Records**: Written documentation of adequate vaccination with polio-containing vaccine in the past. Healthcare providers, schools, colleges, prior employers, or the military (if enlisted) may have records of immunization history. An individual may also be included in their state’s immunization registry. Providers who administer vaccines to patients are strongly encouraged to become New Jersey Immunization System (NJIIS) users and submit administration data. By using NJIIS for all patients, regardless of age, it allows for a single source of documentation for all immunizations administered.

Tips for patients on finding immunization records may also be found here: [https://www.cdc.gov/vaccines/adults/vaccination-records.html](https://www.cdc.gov/vaccines/adults/vaccination-records.html)

**Polio immunization has been available since 1955 and has been part of the routine childhood immunization schedule for decades. Therefore, adults who were born and raised in the United States can assume they were vaccinated for polio as children unless there are specific reasons to believe they were not vaccinated. If an individual thinks they are unimmunized and records cannot be easily obtained, it is recommended that they discuss with their healthcare provider to better understand their individual risk for polio and need for polio vaccination.**

**Polio: Clinical Presentation & Transmission**

Poliovirus is an enterovirus spread primarily by the fecal-oral route and less commonly by respiratory droplets. Most people with infection have no symptoms but can still transmit the virus, and poliovirus infection can lead to aseptic meningitis, paralysis, permanent disability, and death. On average, 1 in 4 infected people will have flu-like symptoms (mild constitutional, respiratory, and/or gastrointestinal symptoms), 1 in 25 will have aseptic meningitis, and 1 in 200-2000 (varies by virus type) will develop irreversible paralysis. Virus persists in the throat for approximately 1 to 2 weeks after onset of illness and is excreted in feces for an average of 3 to 6 weeks, sometimes longer. However, infected people are most infectious during the days immediately before and after onset of symptoms. People who are exposed to poliovirus are at risk for non-paralytic poliomyelitis 3 to 6 days after exposure; paralysis typically occurs between 7 to 21 days after exposure.

**Reporting Suspected Cases of Polio**

Confirmed or suspect cases of poliomyelitis are immediately reportable to the local health department (LHD) where the patient resides, or if unknown, wherein the diagnosis is made. If LHD
personnel are unavailable, healthcare providers should report the case to the New Jersey Department of Health (NJDOH), Communicable Disease Service at 609-826-5964. In cases of immediately reportable diseases and other emergencies and if the LHD cannot be reached, the NJDOH maintains an emergency after hours phone number: 609-392-2020.

For cases of suspect paralytic polio, or when there is a high suspicion of non-paralytic polio (e.g., compatible illness in a contact of a polio case), consult with the LHD to request approval from NJDOH for specimen submission. Polio testing is not available at the NJDOH Public Health and Environmental Laboratory (PHEL) and would need to be sent to CDC. Prior approval is required before submission. While awaiting approval, specimens should be collected as follows (in order of priority):

- **Two** stool specimens: collected 24 hours apart (collected as early in illness as possible, ideally within first 14 days after onset of paralytic disease)
  - 10-20 g, collected in a sterile, wide-mouth container with no additives.
- Oropharyngeal swab AND/OR nasopharyngeal swab:
  - For OP swabs, flocked swabs are preferred. Sterile Dacron or rayon swabs with plastic or metal handles may also be used. Do NOT use cotton or calcium alginate swabs or swabs with wooden sticks.
  - Place the swab in viral transport media (VTM) or universal transport media (UTM).
  - The same swabs and media used for COVID or influenza PCR testing can be used. Do not use saline or send dry swabs.
- Cerebrospinal fluid (CSF): 1-2 mL, if available, in sterile collection tube
- Serum, collected preferably **before** treatment with intravenous immunoglobulin (IVIG): 1mL in red or tiger-top tube
- **Specimens should be stored frozen at ≤-20°C and shipped on dry ice**
- Acute Flaccid Myelitis (AFM) Specimen Collection Guidance can be referenced for polio specimen collection.

Approval is required by NJDOH prior to submission and, upon approval, specimens are generally submitted through the NJDOH PHEL. A completed SRD-1 form must accompany all specimens sent to PHEL.

Other routine pathogen-specific testing should continue at hospital laboratories as determined by the patient’s clinical picture.

### Infection Prevention in Healthcare Settings

Efforts should be made to assess and document poliovirus immunization status of your healthcare staff. Healthcare workers include physicians, nurses, emergency medical personnel, dental professionals and students, medical and nursing students, laboratory technicians, pharmacists, hospital volunteers, and administrative staff.

Only healthcare workers with evidence of complete poliovirus immunization should provide care to patients with poliovirus infection. Healthcare workers who have had three or more doses of polio vaccine in the past and are at higher risk of exposure to poliovirus can get one lifetime booster dose of IPV.
Standard and Contact Precautions should be used, including wearing gloves, gowns, and masks.
