

Clinical Screening Guidelines for Asbestos-Related Lung Disease

Introduction

A physician with expertise in the evaluation and management of asbestos-related lung diseases should screen patients who are now or have been in the past:

- Workers involved in:
 - Mining of asbestos or minerals contaminated with asbestos
 - Manufacturing or using asbestos-containing products
 - Custodial, maintenance and repair work in asbestos-containing buildings, or
 - Direct contact with asbestos-containing waste or dust emissions
- People:
 - Living in the vicinity of asbestos mines and asbestos-related industries such as a vermiculite processing plant
 - In direct contact with asbestos-containing waste or dust emissions

Medical history The medical history interview should include:

- Reason for visit
- Past medical history
 - Include general respiratory, tuberculosis, lung infection and cardiac history, rib fracture, thoracic surgery
- Current respiratory health history
 - Progressive dyspnea on exertion, dry cough, fatigue, weight loss, tachypnea at rest
- Smoking history
 - Include history of past attempts and/or willingness to quit, need for intervention

Continued on next page

| Medical history | General asbestos exposure history |
|-------------------------|--|
| (continued) | Any direct contact with asbestos |
| | Source, intensity, and duration of exposure |
| | Age at first exposure and years since first exposure |
| | Occupational exposure history |
| | Asbestos and other chemical exposures on the job or from hobbies |
| | High-risk occupations such as construction, demolition, remodeling, mining, and shipbuilding |
| | Source, intensity, and duration of exposure |
| | Age at first exposure and years since first exposure |
| Comprehensive | The physical exam should include: |
| physical examination | Auscultation of heart and lungs |
| | End-inspiratory basilar rales |
| | Abdominal examination |
| | • Extremity examination (including clubbing, pulses, peripheral edema, and cyanosis) |
| PA chest radiograph | Note that radiological evidence is typically not present until at least 5 years after first exposure. In addition to a clinical evaluation, the use of a B-Reader is recommended for radiographic rating of lung changes. The radiograph reader should look for: |
| | Pleural changes |
| | Thickening and possible calcification of the parietal and visceral lung pleura Benign pleural effusion |
| | Interstitial changes |
| | Small, irregular opacities in lower lung fields, "ground glass" appearance |
| | Diffuse, bilateral interstitial fibrosis |
| | Lung carcinoma/pulmonary nodules |
| Simple pulmonary | Include FVC, FEV1, and FEV1/FVC ratio. |
| function test (PFT | Asbestosis and some diffuse pleural disease may be characterized by restrictive |
| or spirometry) | changes. Among smokers, a mixed pattern may be noticed. |
| | • Consider pre- and post-bronchodilator, especially if obstructive component is evident. |
| | |

Criteria for further evaluation

- If x-ray is normal or inconclusive and exposure history is positive, repeat x-ray in subsequent years as needed. Lateral and/or oblique view recommended for inconclusive pleural changes.
- Consider referring patients with possible restrictive lung disease, significant radiographic or pulmonary function abnormalities, or those with uncertain significance, to a pulmonary specialist for complete pulmonary function tests and further evaluation.
- CT scan: NOT a screening tool; recommended only if exam/PFT results suggest disease but x-ray does not correlate or if findings of uncertain significance are found on chest x-ray.
- CT may assist in differentiating pleural plaques from soft-tissue densities, cancer versus rounded atelectasis.
